INDEX.

Abdominal; abscess, 347; belt, 386.
Abnormal menstruation, 108.
Abortion as a therapeutic measure, 243.
Abortive treatment of smallpox, 302.
Abscess; perinephritic, 11; of the liver, 181; of abdomen, 347; of tonsil, 347; gonorrhœal, 527.
Abstract of ophthalmological literature, 413, 443, 470.
Accidental deaths, increase of, 442.
Accidents after ovariotomy, 105.
Accommodating muscle, treatment of paralysis of, 162.
Account of nine sclerotomies, 234.
Accumulation of foreign bodies in the stomach, 17.
Accuracy of clinical thermometers, 222.
Acid; *benzoic*, action of, 182; *carbolic*, in hemorrhoids, 96; as an antipyretic agent, 274; in carbuncle, 294; poisoning by, 613; *lactic*, in vesical catarrh, 23; *phosphate*, Horsford's, 167; *pyrogallic*, in hemorrhage from the rectum, 576; *salicylic;* as a foot powder, 162; elixir of, 556.
Acids, mineral, to relieve burns from, 470.
Acne vulgaris, treatment of, 99.
Aconite; in fevers, 525; poisoning from, 616.
Act; medical, for Pennsylvania, 502; relating to color blindness, 559; temperance, in Kansas, 559.
Action; of benzoic acid, 182; of anæsthetics, 275; of electricity, 330; of bromides in epilepsy, 707.
Active principle of hydrastis, 470.
Activity, relation of sexual to cerebral, 50.
Actual cautery, use of the, 53.
Acute; rheumatism, 69, 377, 576; glaucoma, 234; gonorrhœa, cardiac complications of, 498.
Adherent placenta, 349.
Adolphe Gubler's therapeutics, 74.
Adulteration; of drugs, 83; of food supplies, 134; of coffee, 469.
Adults, glaucoma in, 234.
Affection; of the nails, 163; of the liver and stomach of habitual drinkers, 617.
Affections; pleuritic, sudden death in, 321; of the testicle, suspensory bandage in, 673; of the skin in neuralgia, 697.
Africa, medical practice in, 531.
After; pains, chloral in, 68; education of graduates, 327.
Age, old, hygiene of, 424.
Agent; antiseptic, carbolic acid as an, 274; electrical, dried collodion as an, 331.
Agents; therapeutical, 24; digestive, in inflammatory rheumatism, 60.
Aid associations, 357.
Air, detection of carbon in the, 358.
Albuminate of iron in amenorrhœa, 525.
Albuminuria; in healthy men, 128; the pathology of, 393.
Alcohol, antispasmodic effects of, 323.
Alcoholic liquors, their effect on the liver and stomach, 617.
Alleged higher rate of mortality in the medical profession, 157.
Allies of homatropin, 24.
Allocheiria, 691.
Alumni association of Jefferson Medical Col., 335.
Amenorrhœa; albuminate of iron in, 525; sterility and, 634.
Ammonia, intravenous injection of, 411.
Amputation of a finger, 680.
Anæmia, mitral disease, with and without, 207.
Anæsthesia; by compressed nitrous oxide, 44; by rapid breathing, 276; special, 278; in labor, 279; the earliest instance of, 615.
Anæsthetic; narcosis, 278; methods modified, 704.
Anæsthetics; relative action and administration of, 275; mortality from, 278.
Anæsthetizing during sleep, 279.
Anatomical; act in Michigan, 447; guides, tattoo marks as, 496.
Anchylosed elbow joint, 655.
Aneurism of the femur, 119.
Angina pectoris, 550.
Aniline colors detected in wine, 685.
Animals; used for food, diseases of, 352; favus from, 579.
Annual report of the Surgeon General, 75.
Anthrax; bacillus the source of, 49; treatment of, 682.
Antidote to strychnia, 113.
Anti- ; *miasmatic*, eucalyptus as an, 160; *pyretic* agent, carbolic acid as an, 274; *septic;* treatment of empyema, 22; practical methods of, 101; dressing, 133; with eucalyptus oil, 71; methods of Esmarch, 154; removal of scrotal elephantiasis, 295; *spasmodic* effects of alcohol, 323; *syphilitic*, turpentine as an, 192.
Anuria, blistering in, 23.
Aortic and mitral regurgitation, 152.
Aphasia, 22.
Apparatus for extension in fractures, 387.
Apparent insusceptibility to nitrous oxide, 106.
Apparitions, or false conceptions, 218.
Application; of fixed dressings, 35; of the faradic and galvanic currents, 331, 704.
Applications; revulsive, in tuberculosis, 52; topical, of iodoform in orchitis, 528.
Argument, an astounding, 504.
Arsenic in enlarged spleen, 218.
Art, medical, among the Celestials, 697.
Artery forceps, 386.
Artificial; respiration in newborn infants, 126; membrana tympani, 266.
Aspergillus nigricans, 25.
Asphyxia of the newborn, hot baths in, 442.
Association; for the protection of the insane, 250, 265; Northern medical, of Philadelphia, officers of, 280; of Medical Officers of American Institutions for Idiotic and Feeble minded persons, 559; of medical editors, 586; of medical colleges, 586; American surgical, 587; medical, of Georgia, 587.

Asthma, electricity in, 333.
Astigmatism, 318.
Astounding argument, 504.
Asylum; State Lunatic, of Pa., removal of superintendent of, 56.
Asylums, insane, plans for, 614.
Atelectasis, forced respiration in, 701.
Atheroma of the aortic valves and arteries, 401.
Atmosphere, epidemic constitution of the, 634.
Atropia sulphate; in epileptiform convulsions, 70; in wounds of the cornea, 147; prevention of the irritating effects of, 516; in opium poisoning, 708.
Attack of trichinosis, 28.
Aural; department of Jefferson Med. Col. Hospital, brief report, 65; polypi, treatment of, 69.
Autopsy; in sclerema, 54; in typhoid fever, 93.
Away with the spray, 77.
Axillary pad in fractured clavicle, 222.

Babies, hogs *vs.*, 476.
Bacillus as the source of anthrax, 49.
Backache, high-heeled boots and, 684.
Baker's cod-liver oil, 167.
Bandage; plaster-of-Paris, in spinal irritation, 377; galvanic, in hydrocele, 441; suspensory, in affections of the testicle, 673.
Baths; cold, in rheumatism, 100; hot, in asphyxia of the newborn, 442.
Battey's operation, 17.
Bellevue Hospital Medical College weakening, 280, 385.
Belt, abdominal, stem pessary and, 386.
Benevolent societies, statistics of sickness in, 687.
Benzoate; of soda in rheumatism, 442; of calcium, 607.
Benzoic acid, action of, 182.
Bichromate of potash in obstinate syphilis, 193.
Bile ducts; obstruction of the, 401; obliteration of the, 690.
Biliary calculi, hygienic treatment of, 580.
Birth, quintuple, 334.
Births, the limitation of, 382.
Bladder; irritable, in the female, 108; stone in the, 221, 288; drainage in chronic cystitis, 324; disease of the, 424; application of galvanism to the, 704.
Bleeding; local, in inflammation, 76; in tetanus, 406; in eclampsia, 707.
Blindness, color; act relating to, 559; statistics of, 615; in pilots, 699.
Blistering, in aneuria, 23.
Blood, changes in, in acute rheumatism, 69.
Blunders of doctors, 583.
Board of health; the national, 139; effort to establish a, 246; value of, 110.
Bodies; foreign; in the stomach, 17, 359; extracted from the ear, 241; in the uterus, 302; removed by gastrotomy, 329; Pacchionian, office of the, 526; movable, in the knee joint, 580.
Bogus diploma business in Philadelphia, 83.
Bone; femoral, fracture of the, 159; temporal, neurosis of, 431.
Boots, high heeled, and backache, 684.
Born bearded, 167.
Bougie as a tampon, 267.
Boys, incontinence of urine in, 652.
Brain; injury, serious, slight results from, 377; substance, its relation to mental power, 517,525.
Brains, size of, 280, 364.
Branches, special, in medicine, 304.
Breast, cancer of the, 161.
Breathing, rapid, for anæsthesia, 276.
Bright's disease, ophthalmoscopic diagnosis of, 677.
British contagious diseases acts, 699.
Bromides in epilepsy, 707.
Bronzing of the skin, 517.
Brow case, incompetence in a, 110.
Buchanan, "Dr.", 251.
Buildings, public, sanitary rules for, 686.
Burn; severe, recovery from, 81; treatment of, 412; from mineral acids, relieved, 470.
Butterine and winter cholera, 307.

Cæsarean operation, 101.
Calcium, benzoate of, 607.
Calculi; pancreatic, 401; biliary, 580.
Calomel; and chlorate of potash, 224, 364; corrosive sublimate from, 279.
Can syphilis be spread by vaccination with human virus? 52.
Cancer; of stomach, 151; of breast, 161; of rectum, 241; of the tongue, 406; chian turpentine in, 454; mammary, infiltration in, 691.
Cantharides poisoning, symptoms of, 574.
Carbolic acid; in hemorrhoids, 96; as an antipyretic agent, 274; in carbuncle, 294; poisoning by, 613.
Carbon, detection of in the air, 358.
Carbuncle, carbolic acid in, 294.
Cardiac; disease, dropsy in, 237; prognosis in, 515; complications of acute gonorrhœa, 498.
Care of foundlings in Philadelphia, 475.
Carica papaya, 106.
Caries of the spine, 485.
Caruncle, urethral, 627.
Case; a tough, 26; of hemorrhagic diathesis, 44; of hæmophilia, 56; of poisoning with ergot, 69; of diabetes, 82; of typhoid fever, 93; of cæsarean operation, 101; of herniotomy, 118; of tubercular meningitis, 150; of prolapsus, 220; of glaucoma, 234; of convergent strabismus, 263; of gastrectomy, 329; of poisoning by chlorate of potash, 330; of syphilitic disease, 401; of myelitis, 485; of triplets, 531; of double quotidian hemorrhagic fever, 556; of prolonged gestation and unusual labor, 561; illustrating missed labor, 572; of morphine habit, 649; of dystocia, 670; of opium poisoning, 708.
Cases; of syphilis, 13; in mental therapeutics, 16; of exophthalmic goitre, 89; of wounds of the cornea, 147; of diseases of the pancreas, 153; of spinal irritation, 182; of optico-ciliary neurotomy, 316; of trichinosis, 419; of pulmonary syphilis, 427; of hysteria, sudden death in, 575; of compound ganglion of the flexors of the hand, 676; of allocheiria, 691.
Cat, trichinæ in a, 195.
Catalepsy and the faculty of speech, 300, 676.
Cataract, syphilis as a cause of, 191.
Catarrh; vesical, lactic acid in, 23; nasal, 230, 322, 333, 401, 574; intestinal, 345.
Catarrhal; phthisis, 176; diphtheria, 575.
Catching cold, 565.
Causation of the uniformly small pelvis, 412.
Cause; of nephritis after diphtheria, 385; of infant mortality, 409; of rigor mortis, 468; of disease, excessive eating as a, 573.

Causes; of pneumonia, 358; of sudden death in disease, 494; of deaths in Great Britain, 532; of insanity, 640.
Cautery, actual, use of the, 53.
Cavazzini's, case of gastrotomy, 329.
Celestials, medical art among the, 697.
Centenarians, 84, 644.
Cerebral; tumor, 22; activity, 50; rheumatism, 100; hemorrhage, 242; trance, 669.
Cerebrology of criminals, 640.
Cervix uteri; laceration of the, 61; dilation of, 188; chian turpentine in epithelioma of the, 469.
Chancre of the lip, 660.
Changes; in the blood in acute rheumatism, 69; in Marine Hospital Service, 82, 474.
Character of diabetic urine, 55.
Charbon, malignant, germs of, 524.
Charleston, S. C., influenza in, 504.
Charter annulled, 363.
Checking phthisical cough, 356.
Chemical examination of drinking water, 166.
Chian turpentine in cancer, 454; in epithelioma of the cervix uteri, 469.
Child; male, hysteria in a, 188; large amount of opium to a, 446.
Childbed, utero-vaginal injections in, 681.
Children; vesical spasms in, 23; diseases of, 77; typhoid fever in, 281; valvular disease of the heart in, 606; inward fits in, 685.
China, how doctors are made there, 697.
Chloral; in after pains, 68; as an antidote to strychnia, 113, 279; pharmacology of, 160; poisoning by, 221; hydrate, 537; eczema from, 556; in eclampsia, 707.
Chlorate of potash; and calomel, 224; poisoning by, 330.
Chloroform, ether and, 76.
Cholera infantum, lactopeptine in, 699.
Chorea in pregnancy, 188.
Chromicized catgut ligature, 442.
Chronic; peritonitis, localized, 41; nasal catarrh, 230, 322; diffuse nephritis, 290; prostatic enlargement, 322; cystitis, 324; uterine inversion, 441; nicotine poisoning, 578; ulcer of the stomach, 582; affection of the liver and stomach, 617; colitis, 672, 710; intermittent fever, 695.
Cinchona; cutaneous eruption from, 102; trees, 215.
City of Mexico as a health resort, 140.
Classification of lung diseases, 161.
Clavicle, fractured, 222.
Clinical; studies of inebriety, 144, 506; thermometers, 222; varieties and treatment of pneumonia, 645.
Club foot, operation for, 212.
Coca leaf, 616.
Cod-liver oil, Baker's, 167.
Coffee adulterants, detection of, 469.
Cold; baths, in cerebral rheumatism, 100; fire, 217; is it favorable to health? 251; treatment of dysentery, 517; catching, 565.
Colic, sodium phosphate in, 100.
Colitis, chronic, 672, 710.
Collections, purulent, salt water in, 610.
College; commencements, 335, 361; a new medical, 418.
Collodion, dried, as an electrical agent, 331.
Colorado, a strange story from 672.
Color blindness; act relating to, 559; statistics of, 615; painful effects of, 639; in pilots, 699.
Colors, aniline, detected in wine, 685.
Colotomy, value of, 240.
Combination of stem pessary and abdominal belt, 386.
Combinations, explosive pharmaceutical, 50.
Comparative mortality of, 1881, 699.
Complete; extirpation of the uterus, 350; obliteration of the common bile duct, 690.
Complicated; presentation, 133; case of prolapsus, 220.
Composition of podophyllin, 302.
Compound; fracture of radius and ulna, 627; ganglion of the flexors of the hand, 676.
Compressed; nitrous oxide for anæsthesia, 44; hypodermic tablets, 643.
Compresses of hot water in tetanus, 188.
Concentrated solution of quinine, 555.
Concentration theory of trance, 583.
Conceptions, false, 218.
Condition of Malaga, 83.
Conference, international sanitary, 83.
Confessions, medical, 54, 110, 164, 195.
Congenital hydrocephalocele, 53.
Congestive dysmenorrhœa, 412.
Congress; international, of hygiene, 84; pharmaceutical, 588.
Consciousness in epilepsy, 668.
Consumption; of the lungs, relation of sex to, 7; galloping, 179: of diseased meat, 136; of opium in the United States, 438.
Constipation; Swedish movement cure in, 206; psylium seeds in, 555.
Constitution; of human milk, 490; epidemic, of the atmosphere, 634.
Contagion; of enteric fever, 217; mental, 641; from milk, 666.
Contagious diseases law; in Wisconsin, 613; in Great Britain, 699.
Contribution to the study of nervous diseases, 674.
Control of diarrhœa in typhoid fever, 516.
Convalescence, tonic potions in, 610.
Convergent strabismus, 263.
Convulsions treated by sulphate atropia, 70.
Cookery as it should be, 298.
Copaiva in sciatica, 376.
Copper, sulphate of; in croup, 581; in neuralgia, 611.
Cord, management of the, 17.
Cornea, wounds of the, 147.
Correction, a, 671.
Corrosive sublimate from calomel, 279.
Coryza, curious form of, 247.
Cosmetic invention, 616.
Cough; phthisical, checking, 356; ergotin in, 468.
Council, sanitary, of the Mississippi valley, 558.
Cow vaccination, product of, 249.
Coxalgia; diagnosis of, 666; rectal touch in, 707.
Craniomeningocele, 53.
Cremation, 644; progress of, 104; in Rome, 195; society, 419.
Criminals, cerebrology of, 640.
Criterion of hallucinations, 668.
Croup; with tracheotomy, 124; membranous, 151; sulphate of copper in, 581.
Crude petroleum, 697.
Cultivation of cinchona trees, 215.
Cupping, dry, in typhoid fever, 248.

Cupric test pellets, 612.
Curative treatment of smallpox, 302.
Cure; of tabes dorsalis, by nerve stretching, 23; of phthisis, 52; of glaucoma by sclerotomy, 234; of a case of morphine habit, 649.

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

Trade supplied in Philadelphia by

1164-1215eow ROBERT SHOEMAKER & CO.

BURN-BRAE,

A PRIVATE HOSPITAL

FOR

MENTAL DISORDERS.

Location beautiful and salubrious. Grounds extensive and handsomely laid out. Distance from Chestnut Street Bridge, Philadelphia, six miles. Access by Baltimore Turnpike, or West Chester and Philadelphia Railroad; nearest station, Oak Lane.

BURN-BRAE accommodates twenty patients of each sex. Though possessing all the safeguards and appliances of a Public Hospital, the arrangements are domestic and familiar. No efforts spared to make the house a comfortable *Home* for its guests.

REFERENCES.

Professors Stillé, Smith, DaCosta, Agnew, Penrose, Rev. Wm. P. Breed, D.D., Israel H. Johnson, Phila.; W. C. Van Bibber, M.D., Baltimore, Md.

ENDOCARDITIS.

BY ALONZO CLARK, M.D., LL.D.,

President and Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons, New York.

The next topic that lies in our way is endocarditis, and I, perhaps, had better not enter upon that to-day, as the hour has nearly expired, but make a few preliminary remarks upon what is essential to an understanding of endocarditis and valvular diseases of the heart.

Here you observe a heart, a very large one, laid open. You observe the inner surface of this cavity is lined by a smooth, shining membrane. This is called the endocardium. A serous membrane somewhat analogous to that that lies upon its outside. It lines it completely; lines all these muscles, protecting the muscular structure entirely from contact with the blood. This same lining membrane is to be found in every cavity of the heart, and it is continuous in a certain way, from one to the other.

Now observe how a valve is made. Here is the semilunar valve of the aorta. If you will examine this you will see that the tissue is absolutely continuous from the wall of the ventricle on to this valve. Follow it on a little further; it comes over here and doubles down where my finger is; it doubles down upon this valve, and then from there is reflected off on to the base of the aorta. Well, a valve of the heart is made, then, of a duplication of the lining membrane, of a duplication of the endocardium. You see I have illustrated it with this towel. The valve is open when it lies against the aorta, and you can then hardly see how it is constructed; but open it and you see it is the same lining membrane of the ventricle which doubles down to the bottom of this valve and then passes off, without being broken, into the great vessel, exactly as I have folded this towel.

The mitral valve is made in the same way, but there is a variation. The lining membrane of the ventricle goes down upon the posterior face of the mitral valve, as I hold this now; doubles upon itself, and goes back into the auricle, so that that again is continuous. But the peculiarity is that to this valve are attached a considerable number of little cords that go down into the ventricle and are there attached to what are called the fleshy columns—these bodies. The endocardium is no less continuous for that reason. Indeed, it doubles upon these cords, it covers them. Each valve, in each part of the heart, is made in the same way, but there is, however, a little more to each of these valves. There is a fibrous structure in the middle of them—you may say a skeleton; something like the frame of a house before there are any boards or plaster put upon it. Then the fibrous tissue of the valve lies between these two folds of membrane, as my finger lies between the two folds of this towel. Now, it happens that in endocarditis that particular part, that is, the aortic or the pulmonary valve, is most likely to show the results of inflammatory action.

But the point I wanted to bring to your attention was, and is, in what way the blood circulates through the heart, and what the heart does in the course of the circulation of the blood through it.

Suppose the blood is coming in from the lung.

In the period of rest the left auricle is being distended by the blood coming in from the lung. The contraction of the heart begins in the auricle and almost instantly spreads to the ventricle. The result of this little contraction of the auricle before the ventricle begins to contract is to send a little more blood into the ventricle, or perhaps to send a portion of it backward, because there is no valve which will prevent its going either way. Then the left ventricle contracts; what becomes of the blood? It goes right up here into this great aorta, and if there is anything here on this valve to obstruct it it may make a noise, and that is not normal; that is a bruit or murmur. Then, when you have a murmur produced at the base of the heart when the ventricle contracts it is produced by an obstruction—it may be a narrowing of the vessel at the point of these valves. Now, what else, when this ventricle contracts? If there is a way for it to get out any where the blood will take that way, as well as this, its natural way. Suppose this valve, the mitral, is insufficient; suppose it to be diseased in such a way it cannot close perfectly; what is there to prevent the blood, when the ventricle contracts, going back on the very track it came? Nothing in the world. Well, then, when this mitral valve is insufficient, and you get a murmur from it, it will be when the ventricle contracts: that is regurgitation. When in systole, or contraction of the ventricle, there is a murmur here at the aortic opening, that is obstruction, while this is regurgitation.

Now, then, suppose this aortic valve to be so far diseased, so far narrowed and shortened, that the three different portions of the valve cannot meet in the middle of the artery, and stop the blood going back; there would be a murmur then. And when? Why, after the first sound of the heart has gone by, after the contraction of the ventricle has gone—in the period of rest, or in the place of the second sound. A murmur, then, heard at the base of the heart in the place of the second sound, implies regurgitation; a murmur heard during the contraction of the heart implies obstruction. You may have both in the same person, at the same time. Here, again, at the mitral valve, if there is a vegetation, if there is unnatural thickening of the valves, when the blood comes from the auricle into the ventricle during the period of repose, there may be a murmur. It is almost always a very faint murmur, and Dr. Williams described it, a good many years ago, as being like the sound produced by breathing the word *awe*—a very soft blowing murmur. That is in the period of rest; it has been called presystolic. I have no objection to the name; it is before the systole. Then you may have two murmurs at each one of these valvular openings; in which case it is obstruction in the one instance and regurgitation in the other. Now, to satisfy you whether it is obstructive or regurgitative you have only to remember the course of the blood. It begins here in the auricle, passes into the ventricle during the period of rest; then the ventricle contracts and it goes over these valves into the aorta, or, if there is an opening, it goes right back.

SECOND LECTURE.

Here is a large heart—all the better, because it acts just as a small one does, and can be seen at a greater distance. Here is the mitral valve, which is to guard the communication between the left auricle and the left ventricle, and you observe that it is attached at its border to some fleshy columns here, three tendinous cords—three small tendinous cords that run from the border of the valves to the fleshy columns. I will repeat what I said last. The blood we will suppose is here in the left auricle. It has come from the lungs. The first act of contraction is in the auricle, but it is almost immediately followed by contraction of the ventricle. If the heart is in its normal condition, when the left ventricle contracts it will throw the blood past the semilunar valves up into the aorta. If there is a hole here, if the mitral valve does not close properly, we call it insufficiency, and a portion of the blood will go back on the very track it has come; go back into the auricle. That we call mitral regurgitation. Then, too, it sometimes happens, as I shall explain to you further on, that these valves are subjected to a certain amount of inflammatory action when endocarditis occurs, and their action is disordered. The mitral valve, we know, is composed of fleshy columns which are composed of fibres that are continuous with those in the walls of the heart. Now, if these be diseased, one or more of them, or a part of them may become contracted and leave an opening in the mitral valve. This fact shows that regurgitation may take place without disease of the valves; that is, without deforming disease of the valves.

As the blood comes from the ventricles it is forced over the semilunar valves, which lie smoothly up against the aorta, presenting no obstruction to the outgo of the blood. If they are rough, thickened, contracted, then they will present an obstacle to the course of the blood, and there will be produced a murmur during the contraction of the heart, that is, during systole—

the time when you feel the impulse of the heart against the ear when it is applied to the chest. Now, that is easily remembered, I think; the murmur in systole, the murmur in the contraction of the ventricle, heard over that part of the chest which corresponds to the aorta, an aortic obstruction. When the blood reaches the aorta the aorta dilates, and on account of the many little elastic fibres which it contains it has a disposition at once to contract; and in contracting it of course starts the current backward toward the heart, which instantly closes these valves and they prevent its return. But if these valves have become so thickened, so hard and inelastic that they will not close, a portion of the blood is sent back into the ventricle, which has to do its work over. This produces a murmur which occurs during the period of repose or in the place of the second sound. This constitutes aortic regurgitation. We often have obstruction and regurgitation in the same person, so that we will have a "whewing" sound during contraction, which is repeated during diastole of the ventricle. It has come to be the fashion latterly to use the terms "direct" and "indirect." I do not think the terms are nearly as good as obstruction and regurgitation, for these are descriptive, while only "direct" can be regarded as descriptive in the other choice of terms.

Then the blood goes on in the general circulation and comes back in the veins to the other side of the heart, to the right auricle. The right auricle in turn contracts after it is full and sends its blood into the right ventricle, which, being connected with the left ventricle by their septum, is really a part of the same organ and liable to contract at the same time; and the right and left ventricles then do contract at the same instant, and a sound produced by the passage of blood into the pulmonary artery occurs in diastole. You observe that the pulmonary artery has valves corresponding with those of the aorta, and they work in the same way. In this particular specimen they are in a healthy condition, and you can observe how delicate they are. You cannot recognize them by touch. They fall up against the artery and allow the blood to flow over them easily and freely. But these, too, are sometimes found to be diseased. The valves of the right side of the heart, I say, are sometimes found to be diseased, and here is as good a place to state the fact as any, that in persons who have disease of the right side, if it is not due to laceration or breaking of its tendinous cords, you may pretty reasonably infer that the disease belonged to the period before birth. The right side of the heart is more subject than the left to disease in utero. The left side of the heart becomes diseased after birth. If you can find a murmur, then, that belongs to the pulmonary valves, you will be pretty sure to find it in a child, and it will be pretty safe to infer that there was endocarditis in that child before it was born. It is not a common occurrence, and yet it has happened a few times in my own observation. Then the same law applies to the current of blood and to the sound that will be produced by disease of the valves of the right side as on the left. There are two valves here, the tricuspid, which guard the opening between the auricle and ventricle, and act in the same way as the mitral valve on the left side and the pulmonary valve.

Now, I will repeat the formula by which you can recognize disease at different points of the heart. Notice that these fleshy columns are connected with the heart at a distance of from one inch to an inch and a half above its apex; in this heart it is fully an inch and a half. These tendinous cords run into the heart, and may be regarded as a conducting medium, and the fleshy columns also may be regarded as a conducting medium. The point where, physiologically, or in audition, you can get nearest to the heart, is not at the apex exactly, but about an inch above. There you will be more likely to hear sounds produced in the mitral valve than at any other part of the chest; and when I say "heard at the apex," I mean at the apex, or an inch above. When, then, you have a murmur during the time the ventricle is being filled, you ascertain, by listening at different points, where it is most distinct. If it is most distinct at or near the apex in systole it is a murmur of regurgitation by the mitral valve; if, on the contrary, it is heard in the period of repose, in diastole, during this period of repose the blood is flowing from the auricle into the ventricle, and that will be an obstructive sound in the mitral. The mitral is roughened, and throws the blood or itself into sonorous vibrations, as the blood flows over it; that, however, is almost always a very feeble sound. As I said before, Dr. Williams described it by breathing the word "awe," opening the throat well and breathing a little loud.

A murmur heard most distinctly on the third rib, at the sternum, and heard in systole, must be obstruction at the aortic valve. Then, if it is repeated immediately afterward, in the interval—you can hardly appreciate it, and yet you do appreciate it, that there are two sounds—the latter is regurgitation; the valve acts insufficiently, it cannot perform its office, and gives the mur-

murs. Every little while you get two murmurs. I have heard four in the same person, two produced at the aortic valve, two at the mitral.

Now, the same law applies to the right side of the heart. You listen to the right side of the heart, at the lower part of the precordial region on the right side. I do not say the lower part of the sternum, because the sternum extends below the heart region; but on the sternum at the fifth rib, and outside the sternum a little, on the same level, you will get a sound from the right heart more distinctly than anywhere else. If, then, you get a murmur in that region, heard most distinctly in contraction of the heart, in systole, that would be regurgitation by the tricuspid valve. If, on the contrary, you get a murmur which you are not quite satisfied is aortic, and it is a little to the left on the sternum, you may, perhaps, conjecture that it belongs to the pulmonary artery. The pulmonary artery is given off a little further to the left than the aorta, that is, this way; and you listen for the aortic murmurs on the middle of the sternum and a little to the right; for the pulmonary murmurs on the left edge of the sternum and a little to the left of the sternum. If you get a murmur there in systole it is obstruction at the pulmonary valve. If it is repeated, it is then regurgitation at the same valve, and is heard most distinctly at the base of the heart. But if it is tricuspid you will hear it most distinctly on the right part of the heart, at the right edge of the sternum; I never have heard a direct or obstructive murmur at this point. Indeed, a good many years ago Dr. King thought he demonstrated, and probably he did, that this particular part of the heart, the opening of the tricuspid valve, has considerable power of dilatation without injury, and when the veins are over-crowded with blood, surcharging the left ventricle, he says the right ventricle has the power of sending it back into the veins again through the tricuspid opening and without a murmur. I can easily comprehend that it may be so. It is what he called the safety-valve arrangement. The right ventricle being over distended the right auriculo-ventricular opening would be dilated also, and a part of the blood can be thrown back into the veins of the general system without being compelled to go forward into the arteries that lead to the lungs.

Now, then, with reference to the tones of these murmurs. You hear them in different stages of cardiac disease; mildly when the valves begin to be deteriorated; more strongly when the deformity has become considerable. And then again, perhaps not at all after the disease has continued for a length of time and the heart has become weakened by it. Almost every person who has cardiac disease which finally terminates fatally reaches a period, before death, when the murmur cannot be heard, and the simple reason is that the heart cannot contract upon its contents with sufficient force to make the blood run swiftly enough to cause a murmur. It is probable these murmurs are made in the solid tissue and not in the blood itself. The vibrations that produce the murmur are probably in these deformed valves. You have a great many terms by which to designate these murmurs, according to their tone. The French have used terms which represent a filing sound, a rasping sound, a sawing sound, which, of course, are harsh, and given to distinguish the harsh sounds from those which are soft and blowing. But it is not necessary for you to learn those terms. The coarse sounds are almost always produced by deformity or defects of the valves. The blowing sounds are often produced by the same thing, but they are also produced under circumstances in which the valves are not diseased; when, for example, the blood becomes watery and thin, by a law which I cannot explain to you, the blood makes a noise in going over the aortic valves. It is the anæmic sound; and, therefore, if you hear a blowing sound at the aortic opening, as if it were obstructive, your next business is to look in the patient's face and see if she is anæmic—for it occurs more frequently in women than in men. If the face is pale and watery, has a chlorotic look, you will be very likely to get a soft murmur—a blowing murmur at the aortic opening—and it will not authorize you to infer that there is any disease of the aortic valves under such circumstances. There is another thing connected with the thin blood which may perhaps help you to distinguish the sounds that are produced by deformity of the valves and those that occur when the valves are sound. In most of these persons in whom anæmic murmurs occur there will be heard, through the stethoscope applied over the jugular vein in the neck, a continuous humming noise. They call it *bruit de la toupie*, which a friend of mine has interpreted with a little liberty "devil of a noise." This *bruit de la toupie* is not the work of the devil. The French have a little toy which children whirl around, and as it goes around a spring works on a wheel of cogs and makes a repetition of clicks. That is the devil that this is compared with—*bruit de la toupie*. That, of course, is not connected with disease of the heart, but as it so frequently occurs in anæmic persons it is

worth while to associate it in this connection. The harsh, rasping sound is almost always produced by some defect of the valves; the soft, blowing murmur may be so produced, but it is occasionally found in persons whose hearts are sound enough but whose blood is diseased or in a watery condition. I do not think there is any practical use, therefore, in making any other distinctions between the murmur that is soft and the harsh or blowing and rough.

Now, there is another thing that I must call your attention to before entering upon endocarditis itself, associated with the things that I have been explaining. The heart itself has two sounds. They are denominated first and second, and it will interest you to know what is the cause of these two sounds; and, perhaps, as great diversity of opinion has been expressed in regard to the cause of them, it may be of some little interest to you to know which of them I have chosen, as I have been pretty familiar with heart disease. In a few days I shall have a microscopic specimen of the muscles of the heart to show you. It is not ready yet. In that I can show you the different layers of muscular tissue in the heart; show you how some run at nearly right angles to others—indeed, quite at right angles sometimes. I cannot show you how they are braided together, for before the specimen could get around the class it would be lost; but you can infer it from a part of the material of which the house is built. I can show you repeated instances in which some muscular fibres go in one direction, and other fibres at right angles to them. The consequence of this arrangement of fibres is, that as the heart contracts all these bundles of fibres contract at the same time, and one rubs against another. It is not exactly a fiddle-string operation, and yet it is not without analogy to it. These fibres cannot rub upon one another actively, as they do when the heart contracts, without producing some sound, and this first sound continues during the contraction of the heart. It begins with the beginning and ends with the end of that contraction, that is, of the ventricles. The auricles are placed a little out of your reach, so that you cannot know what is going on in them by audition. You can imitate that sound very closely by placing the stethoscope upon the ball of the thumb and opening the thumb in this manner. You will get in your ear a sound exactly like that that you get in the first sound of the heart. Another very good illustration of it is, to place the arm against something that is firm and extend and contract it, and let your chum listen to the action of the muscles.

It has been said that the first sound is produced by the tension of the mitral valves in consequence of the sudden jerk made upon them by their muscular columns. I do not know that that does not enter into the first sound and make a part of it; I do not know that it does. It has been said, again, that the first sound is produced by the rush of blood from the auricle into the ventricle(?). I do not know but that aids in the production of the first sound, and I do not know that it does. The current is easy, the flow is at a pretty good rate, to be sure, and I should not be surprised if its concussion against the empty walls of the ventricles would produce some effect of that kind; and yet I do not know it.

I think when you have tried these little experiments I have spoken to you of, and then listen to the heart sound, you will be pretty well satisfied that the chief element in it is the contraction of the muscles, and the rubbing of these cross fibres one against another. They are separated, to be sure, by a little layer of connective tissue, but even that is put upon the stretch by the action of these muscles that are working at right angular contraction. The first sound, therefore, is confined entirely to the systole, to the contraction. The second sound there are no debates about; experiments have been performed that explain that perfectly. A number of physicians in London tortured some honest old asses and worn-out horses, by opening into the chest and having little hooks that were sharp enough to penetrate the tissue, laying the hook handle along the course of the aorta and penetrating it, then carrying the hook forward and getting it over one of the folds of the semilunar valve and drawing it back up to the wall of the artery. It is an experiment that can be pretty easily done. The result of the experiment was a cessation of the second sound. Then by depressing the handle and raising the point of this hook the valve would be let loose, and be at liberty to play again, and then the second sound was reproduced. They repeated the experiment a great many times, and in a great variety of ways. A Philadelphia committee of doctors repeated it with the same result, so that we have the fact pretty well ascertained, that the second sound, which you will recognize as instantaneous as a click, results from the falling together of these three segments of the valve in the centre of the aorta—a noise of exactly the same kind that I produce now by striking my fingers together. Then you would naturally expect, if these aortic valves are incompetent, are inefficient, do not guard the opening, that there would be no second sound. But call to

mind the fact that I just now said to you that the two hearts beat at the same time, and it is almost never found to be a fact that the pulmonary valves and the aortic valves are diseased in the same person. You have, then, the pulmonary valves to give you the second sound. The aortic valves may not participate in it, may not fall together at all; they may be too short and too inflexible. The cause, then, of the two sounds of the heart you can easily carry in mind. The reflux of the blood from the aorta in its attempt to get back into the ventricle closes, as I told you, these valves, and they close with a click, and that is all there is of the second sound.

Now, we are ready to pursue our course on endocarditis. I have gone into this explanation of the action of the valves, and the effects of their not working properly, because endocarditis is a deformer of valves.

When inflammation occurs in the endocardium, we are not sure that it affects the whole extent of the endocardial membrane. We are sure that it occurs a good deal about the valves. I have not seen for a few years past a heart which I used to show, in the left ventricle of which there was a perfect layer of false membrane attached to the natural tissues, a lining inside of it, of a membrane that could be easily torn off, and was in a great degree torn off by frequent inspection. When we first received it it was perfectly lined by this false membrane. It seems that such specimens are rare, for you find no mention of it in the books, or at least I have seen no mention of it, and the tendency of persons who write about diseases of the heart is to confine the inflammatory action to the valves. Now, it is not necessary that the inflammatory action should be confined to the valves, even from what we see. If there is an exudation upon the border of the ventricle, here, for example, on this part of the endocardium, it will be washed off by the current of blood that is continuously flowing, and flowing with a good deal of force, through the heart. You ask why it would not be washed off from the valves? Because it holds fast there. The effusion is between the folds that make the curtains of this valve, on the attached surface of these folds, and it cannot readily get out. Then there is a form of inflammation, called ulcerative endocarditis, that attacks any portion of the endocardium. I will explain that further on. The point, then, I make is, that because the results of the inflammation are found only in and about the valves, it does not follow that the whole endocardium may not have been the seat of disease.

Then the question occurs, what changes take place in the endocardium during this process? I do not know whether it becomes red, except by analogy. Nobody has ever seen the endocardium at the commencement of endocarditis. We cannot say, then, that we know the membrane is red. We can infer it is probable, because membranes that are inflamed anywhere else, so far as we know, are red at the beginning of the inflammatory process, becoming less and less red as the inflammation exhausts itself. Roughnesses are not commonly made, except in particular kinds of inflammation, upon the body of the endocardium, but here at the valves. Now, then, the kind of production that you may expect from endocarditis is, first, a thickening of the valves; and second, a growth, either upon the valves or near them (and this is not constant), of little eminences—little granulations, you might call them—which are described as being firm at the base, and by microscopical examination found to be composed of connective tissue at the base, but of new and soft cells at the top, so that the base of these little granulations is firmer than the apex. You will see some of them figured in this engraving, and here they make a sort of ornament—to our eye only, not to the patient's—a sort of ornament just below the edges of the aortic valve. Here are some of the same kind of things, with an addition, too, and that addition is the most important fact, perhaps, in the whole history of endocarditis. Little granulations are formed upon these valves, as in that instance, and then the blood has precipitated its fibrine upon these rough surfaces. You are, perhaps, aware that if, in an animal, a thread be run through a vein or artery so as to pierce it about its middle, the fibrine will collect upon that thread and form a clot, a considerable little ball; or it will be swept in the direction of the circulation. Any rough body in an artery, or in the heart, or in a vein, will cause a coagulation of blood about it, the fibrinous portion of blood making the clot. Well, here this roughened surface has become encrusted, so to speak, or covered by a coagulation of fibrine, having some blood-coloring matter in it to give it a red color. Now, that is the worst thing that can happen in endocarditis, for the reason that these concretions, these aggregations upon any rough surface of the heart, are apt to be washed away and carried into the organs of the body—into the brain, not infrequently; perhaps more frequently than into the spleen; rarely to be found in the liver, because the liver circulation from the heart direct is feeble (one small artery), being supplied chiefly by the portal circulation. But the brain lesions

are the worst, and this embolism carried from the heart valves most frequently, or from any portion of the heart, to the arteries of the brain, will frequently produce apoplexy, of course, a pretty grave matter. Then the principal points to be noted with reference to the effect of endo carditis are: First, thickening of the valves by an effusion between their folds; and, second, these granulations growing up in different parts of the endocardium, mostly upon the valves which have lain traps and caused a deposit of fibrine of blood upon them, making what we usually call vegetations, and these are constantly apt to be washed off and carried into important parts of the body and do serious harm.

Now, the material that produces the thickening of these valves is not exactly like ordinary false membrane. The inspection of it by the microscope, when it is recent, shows that it is a transparent, opaquish fluid, filled with new cells, not of the kind that we refer to pus, but of those that are suitable of combining and being propagated into fibrine. The false membrane met with in endocarditis is made in a different way from ordinary false membrane, with which you have already become somewhat familiar. It has no property of its own. It is coagulated into fibres by the addition of acetic acid; at least, Virchow says so, and he compares it with mucine. This product may, at first, swell the valve considerably, and afterward contract by the absorption of its fluid part, and then it may become organized within the two folds of the valves. Well, what will be the result of that? Quite a thickened and clumsy valve. And as this new material contracts it contracts the valve, the valve is shortened so that it cannot reach its fellow in the middle of the artery, and it is very much stiffened and hardened; it is of the consistency of leather sometimes. I shall show you some specimens that will illustrate that point. Now, that defect is the cardinal one. The valves are thickened, they are shortened, they are stiffened, they cannot perform their office. The result of that is, obstruction, and again, regurgitation, one or both, as may occur in a particular case.

Now, then, with reference to the recognition of these changes as they are coming on. You sometimes can do it, and sometimes cannot. Endocarditis is very apt to occur with pericarditis, and while you may be able to recognize pericarditis to your full satisfaction, you will be lingering in doubt, very likely for some time, whether there is endocarditis or not.

One point I passed over. There may be a grade of inflammation of the endocardium and of the valves that will not produce this mucine matter, but merely œdema. The valves may become thickened by becoming bags of water. Now, that is a form of disease that is sometimes recognized, not by the rational signs. To recognize an endocarditis by rational signs is impossible, and perhaps that is a good reason why it waited to be recognized during life till auscultation became an art, and it may, in that sense, be called the child of auscultation. The deformities of valves were known long before auscultation was practiced, but how to recognize endocarditis waited for auscultation. Now, when this œdematous effusion occurs, the valves are obstacles to the free flow of the blood, and produce a murmur. If, then, you have listened at a particular time to the heart and found no murmur of any kind, and you have symptoms of a very vague kind, and you suspect endocarditis, if you listen again you may possibly hear an endocardial murmur, and it is very likely to be at the aortic opening.

(To be Continued.)

Communications.

THE RELATION OF SEX TO CONSUMPTION OF THE LUNGS.

BY T. S. SOZINSKEY, M.D., PH.D.,
Of Philadelphia.

The bearings of sex on the occurrence of consumption of the lungs is a subject on which, so far as I know, very little has been written. In the series of lectures on the disease, by Dr. Pepper, which was published in this journal last summer, not a word was said about it; nor is it referred to in Flint's, or Roberts' treatise on the practice of medicine, or Parkes' on hygiene. Dr. Bristowe disposes of it, in his work on practical medicine, as follows: "The influence of sex is uncertain."

The remarks which precede might well lead one to believe that sex has little or nothing to do with the occurrence of the disease. Yet in a book of mine recently published ("The Care and Culture of Children"), in which, by the way, considerable attention is given to the mortality and allied features of diseases, may be found the following remarkably striking passage: "Between ten and fifteen years of age the deaths from it [consumption of the lungs] are twice as numerous among females as males, and between fifteen and twenty well on to three times as numerous." Evidently either this statement must be untrue or sex has in some way not a little to do with the occurrence of the disease.

Now, I may say that the statement of mine just quoted is indeed somewhat open to criticism. I am disposed to modify it so as to make it read as follows: Between ten and fifteen years of age the deaths from consumption of the lungs are twice as numerous among females as males, and between fifteen and twenty well on to twice as numerous. Still, according to the official Report of the mortality in the United States during the Census year ending June 1st, 1870, of the deaths of persons of from fifteen to twenty years of age due to the disease it appears that in Alabama eight were of males and thirty-six of females; that in Rhode Island fourteen were of males and forty-three of females; that in Delaware four were of males and thirteen of females; that in Connecticut twenty-two were of males and fifty of females; and that in Kentucky seventy-two were of males and one hundred and seventy of females. In about a third of the States, of the deaths of persons of from fifteen to twenty those of females were considerably over twice as many as those of males.

It may be taken as a fact, then, that among persons of from ten to twenty years of age about twice as many females as males die of consumption of the lungs. This being so it is assuredly worth while to examine and see what the relative mortality of the sexes at other periods of life is, from it.

The following table gives the mortality of either sex at different periods of life, from consumption of the lungs, in the United States as a whole and in the States of Pennsylvania and Massachusetts during the Census year ending June 1st, 1870:—

Period of life.	Mortality in U. S.		Mortality in Penna.		Mortality in Mass.	
	Males.	Females.	Males.	Females.	Males.	Females.
Under 5	2274	2209	234	235	178	192
5—10	459	494	35	45	25	44
10—15	501	1056	51	75	32	67
15—20	1756	3431	200	317	125	288
20—25	3938	5138	385	508	290	394
25—30	3904	4684	464	515	284	360
30—35	3329	3556	353	391	227	246
35—40	3262	3215	368	312	218	231
40—45	2631	2422	278	273	164	169
45—50	2423	1843	288	189	147	135
50—55	2130	1655	233	176	124	134
55—60	1657	1221	198	116	106	112
60—65	1704	1407	182	147	145	118
65—70	1341	1172	153	136	88	92
70—75	1118	993	139	125	92	89
75—80	745	696	90	84	50	61
Over 80	726	706	77	72	59	69

From the above table it would seem that, as a whole, in persons under five years of age the mortality from consumption of the lungs among males is greater than among females. In all, or nearly all constitutional diseases this is the case, I believe.

From five to ten years of age females are more liable to have the disease than males. This is markedly the case in Massachusetts; in which State the deaths from it among the former are almost twice as many as among the latter.

Among persons of from ten to fifteen over twice as many females as males succumb to the disease. This statement does not hold good in Pennsylvania.

Among persons of from fifteen to twenty nearly twice as many females as males are destroyed by the disease. The proportion is considerably less than this in Pennsylvania.

The figures given show, therefore, that as stated above the deaths from consumption of the lungs among persons of from ten to twenty years of age consist of about two females to one male. Indeed, among persons of from five to twenty this is nearly the proportion at least in the State of Massachusetts. The proportion of girls to boys who die from it is far greater in that State than in Pennsylvania.

In this connection I may say that of the deaths from the disease in Philadelphia, of persons within their twentieth year of age, there were, in 1876, one hundred and thirteen males and two hundred and nine females, in 1877 one hundred and eight males and one hundred and seventy-one females, and in 1878 one hundred and fourteen males and one hundred and ninety-four females. The published mortality statistics of that city afford no more information than this, as to the number of deaths of either sex from it at different periods of life, except the number of those of each collectively, in persons over twenty years of age.

Returning now to the table above, I would remark that among persons of from twenty to twenty-five about a quarter more females than males die of the disease. In both Pennsylvania and Massachusetts a third more females than males die from it—the proportion being at this period about the same in the two States.

Among persons of from twenty-five to thirty about a sixth more females than males die from the disease. The proportion is less than this in Pennsylvania but greater in Massachusetts.

Among persons of from thirty to thirty-five, about a twelfth more females than males die from the disease, not only in the nation at large, but in both Pennsylvania and Massachusetts.

From the age of thirty-five forward there are more deaths of males than females from the disease. This statement holds good as regards the deaths from it in Pennsylvania, but not in Massachusetts. From forty-five to fifty, from fifty to

fifty-five and from fifty-five to sixty, a third more males than females die from it. In Pennsylvania, the deaths of males are over a third more than those of females, at each of these periods; while in Massachusetts the number of deaths of females is somewhat greater than that of males at each period.

The entire number of deaths of males from the disease during the Census year in the United States was 33,971, and of females 35,925. In Pennsylvania the deaths of males numbered 3750, and of females 3731; and in Massachusetts the deaths of males numbered 2355, and of females 2802. From these figures it would appear that as a whole there is a considerably larger number of deaths of females than of males from the disease. This is emphatically so in Massachusetts, but in Pennsylvania the number of deaths of either sex is almost the same. Of the deaths from the disease in Philadelphia in 1876 there were 1288 males and 1388 females; in 1877 there were 1142 males and 1207 females; and in 1878 there were 1154 males and 1337 females.

Almost every practicing physician must, doubtless, have observed that the number of cases of consumption of the lungs in females is greater than that of males in early life, but not many, probably, suppose that the difference is so marked as the figures given indicate.

Now, how is the greater prevalence of the disease among females than males in childhood and youth to be accounted for? Sex, *per se*, may have something to do with it, but I believe that the mode of life is the main cause of it. Were the young of either sex brought up similarly it is improbable that the deaths of the one would greatly outnumber those of the other. Girls are not generally allowed to exercise as freely as boys, and are confined more closely within doors. From the fifth, or sixth year of age forward their entire plan of existence is very unlike that of boys; and that it is less hygienic scarcely admits of any doubt.

The greater proportion, as regards sex, of deaths of young females in Massachusetts than in Pennsylvania cannot be easily accounted for. Assuredly, some climatic, or social influence, or influences of both these kinds are at work to produce it.

The greater number of deaths of males than of females from the disease among persons of middle age is remarkable. It would seem to indicate simply that the mode of life of the former is less in harmony with their environment than that of the latter.

The much greater proportion, as regards sex, of deaths of males of middle age in Massachusetts is very singular. Possibly, I should say that the greater proportion, as regards sex, of deaths of females of middle age in Massachusetts than in Pennsylvania is very singular. The fact that there is a slightly greater proportion of women to men in the former than in the latter State may have something to do with the matter, but, doubtless, this is only one of the reasons for it.

That consumption of the lungs is largely due to other than hereditary causes is very clearly indicated by the figures given above. The strange features of the mortality from it, of either sex, in Pennsylvania and Massachusetts, which have been pointed out can hardly be, to any great extent, due to influences of an hereditary nature. Unhygienic living is beyond all question the chief source of the appalling mortality from this, the most fatal of all diseases. Constitutional degeneracy, induced by breaches of the laws of health, is the fount, *par excellence*, not only of consumption of the lungs, but of the majority of other diseases.

Such information in respect to the disease as that which precedes serves to show that through individual efforts the ravages of it might be greatly lessened. Were children reared intelligently and so instructed that in after life they should know how to preserve and foster health and strength, the average vigor and longevity of the race might be very considerably increased. There is a pressing need for an apostle of health among us whose words might be heard and heeded by the multitude.

At least one important lesson as to the treatment of the disease in its remediable stage may be drawn from the above considerations; which lesson is this, that in such measures as will improve the general health lie chiefly the means of cure. This truth is far from being as well known as it should be. Hundreds, nay thousands, die of the disease yearly, from the fact that precious time has been wasted, in their cases, in the search for purely medicinal means of cure. Nor have medical practitioners in general nothing to do with this. There are multitudes of them who seek but little anywhere, except in the stores of apothecaries, for the weapons by which to strike powerless this fell destroyer of mankind. And one hears almost daily of experimental searches for remedies among articles which a person of a little common sense would at once cast aside as void of special virtues. To day a disagreeable substance—blood, for instance—which cannot in the nature of things be of more account than any of many ordinary items of diet, receives the ephem-

eral confidence of the profession, as having in it, at any rate, the promise of great things, and to-morrow something else. All of which goes to prove that when unguided by enlightened reason a man cannot practice medicine to much purpose, so far as the welfare of his patients is concerned.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

A CLINICAL LECTURE, DELIVERED MAY 8, 1880, BY WILLIAM PEPPER, M.D.,

Professor of Clinical Medicine in the University of Pennsylvania.

REPORTED BY WM. H. MORRISON, M.D.

A Large Pleural Effusion of the Left Side.

Gentlemen:—I bring this patient again before you to discuss the further stages and treatment of her condition. It has been now about a month since you saw her. You will remember that she had a large left-sided pleural effusion, where the nature of the effusion was open to some doubt. Soon after coming in she had an abrupt rise of temperature, of brief duration. We came to the conclusion that this fever, which was accompanied by a severe attack of strangury and other symptoms of irritation of the kidneys, was due to the action of a large blister. Previously the temperature had been low and the general symptoms did not indicate that the effusion was purulent. At the same time, I called your attention to the fact that this acute attack of fever indicated a sensitive state of the system, in which there would be a predisposition to unhealthy complications.

Since then the course of the case has been peculiar. The action of the blister caused a decided reduction of the effusion. This may be taken as positive proof that at that time the effusion was severe. I am sorry to say that this condition did not continue, but after we had gotten resonance down to the second interspace (dullness had before extended to the apex) after the temperature had fallen to 99°, five days after admission, it again went up to 102°. Since then the evening temperature has never been normal. The temperature has ranged between 99.5° in the morning, to 101°, 101.5°, and occasionally 102°, in the evening, indicating a constant remittent fever of a hectic type. This has been going on for about three weeks. I must acknowledge that lately this febrile action has een growing less, and for the last five days we have had a morning temperature approaching 99°, and an evening temperature a little below 101°.

Our treatment during this time has consisted of the applications of successive blisters. Three large blisters have been applied, first on the front, then on the back, and then on the side. These have been applied at intervals of about a week. The internal treatment has been iodide of potassium and digitalis. She has been kept absolutely at rest. We have tried to control the fever by quinia, and have given her a good nourishing diet.

I have not examined her chest for a little while, but I think the time has come to decide whether or not to perform paracentesis, and I have brought her before you to-day to settle this question.

Her general aspect is good; her expression easy. The tongue is clean, except a slight coating at the back. Her appetite is pretty good, and her bowels regular. On percussion, the resonance is good down to the third rib; there is some resonance at the fourth rib, but at the fourth interspace there is flatness. As she sits up the level of the dullness does not vary more than half an inch. Posteriorly, the dullness extends higher than in front. On auscultation over the right side there is a perfectly healthy respiratory murmur; on the left side there is a respiratory murmur heard all down the back. You will observe that I directed her to open her mouth and not make a noise in breathing. This is a little matter, but one of extreme importance in determining the existence of a pleural effusion. You may have a large effusion filling the whole chest, but to your surprise, on auscultation, you will hear a blowing sound—bronchial breathing—which may seem quite close to the ear, and you may conclude that instead of having a pleural effusion, you have a consolidation of the lung. This blowing breathing may be due to the tracheal sound transmitted through the tense chest walls, at least, that is the way I think it is transmitted, for the ribs are raised and the intercostal tissues are on the stretch, so that the loud breathing is carried either through the liquid or the chest walls to the ear. Before deciding that you have bronchial breathing be sure to see that the patient is not making a blowing sound in the chest.

Now, in the present case, when she was making a noise in her throat in breathing, the sound was transmitted very distinctly to the ear; but when I stopped that I heard vesicular breathing, not perfectly natural, it is true, but still distinct and of a slightly blowing character.

You will observe, then, dullness behind, to the spine of the scapula, a little higher than in front, and when raised from the recumbent posture the line of dullness does not materially change, as it would if the liquid were free to move. We have to deal here with a mass of plastic lymph over the back of the chest, which is not considerable enough to entirely compress the lung, but allows it to expand slightly. In other words, the absorption of liquid has been going on satisfactorily, but it has left behind a large quantity of plastic lymph.

Our line of treatment is, therefore, very plain. There is no excuse for operative interference, for in spite of the febrile temperature, the absorption has been going on satisfactorily. The same irritation that has caused this deposit of lymph has, I think, been the cause of the remittent febrile action. This woman is getting better and the effusion is being absorbed, but it will take a long time for the absorption of this plastic matter. I have found dullness, imperfect respiratory murmur and impaired movement remain for many weeks, and even months, dependent upon a large amount of plastic matter.

This case is a very instructive one, as showing

us that we should never be guided entirely by the irritative fever as indicating pus in the chest, but that we should combine with this a careful study of the other symptoms and the effect of treatment.

I shall put another blister over the back as soon as she can bear it, and continue the use of digitalis and the iodide of potassium.

Peri-nephritic Abscess.

The next patient, a miner of Luzerne county, applies, with the following brief statement: He has been troubled for some time with an abscess, discharging in the back. The origin of this abscess is open to a good deal of doubt. When four years old a calculus was passed by the urethra. When twelve years old another was broken up in the urethra and washed out. Since he was thirteen years old there has been pus in the urine. The amount is now quite considerable. Six years ago he noticed a lump in the left lumbar region, which proved to be an abscess, and opened five years ago. It has discharged ever since. There is no pain complained of. Pain is not caused by rough riding, jumping, etc. He says that some portions of stone were taken from the opening in the back, last January.

This appears to be a case of peri-nephritic abscess, connected with calculous pyelitis, with perforation of the pelvis of the kidney and the escape of fragments of stone into the peri-renal connective tissue, opening later in the lumbar region; a rather unusual condition. This opening is not in the common place for a discharge from caries of the vertebræ. It is outside of the line of the erector spinæ muscles, and some distance above the crest of the ilium. Although a vertebral abscess may burrow through the connective tissues, and escape outside of the fascia. and perforate in the lumbar region, yet it is not commonly so far out as this; still I should not attach too much importance to the locality of the opening. You know that many of these abscesses from diseased vertebræ become psoas or iliac abscesses, and burrow down and appear anteriorly.

This patient has presented to us none of the symptoms of vertebral caries. There has been no spinal tenderness. There is no scrofulous or tubercular diathesis or condition present. Physical examination of the vertebral column has not shown us any lesion there, and the history of the case points in an entirely different direction.

It points very strongly to some calculous and nephritic trouble. Thus, as early as the age of four he passed a calculus by the urethra; eight years later another lodged in the glandular portion of the urethra, and was removed by breaking it up and washing out the pieces. Subsequently pus appears in the urine, not from cystitis, but evidently from inflammation of the higher parts, the ureter and pelvis of the kidney. Later still an abscess forms and discharges in the back, from which opening fragments have been taken. which, unfortunately, have not been preserved, but they are said to have been calculous in their nature, and not from caries of the bone. Much information would have been gained from these fragments, but the course of the case and the absence of marked symptoms of spinal trouble cause me to regard this as an abscess around the kidney, from perforation of the pelvis and the discharge of fragments of stone, or other irritating matter.

If this is so, this is one of a class of cases which have recently been made the subject of some daring operations in surgery, of a character to which I cannot altogether give my consent. For instance, an incision has been made in the lumbar region, the pelvis opened, a calculus extracted, the parts carefully washed out and the urinary fistula thus formed allowed to heal, and the patient restored to health, after years of suffering from the exhausting drain of pyelitis. Not only that. Of course, a peri-nephritic abscess should be opened, but in some cases, after the abscess has been opened the substance of the kidney has been found inflamed and destroyed, and the kidney has been removed, the ureter tied with the animal ligature, and one or two cases have terminated in recovery, but this has led to the operation being performed in cases which have resulted fatally, and where the patient's life could have been made comfortable without the risk of so dangerous an operation.

The first question to be determined in any case is the diagnosis of calculous pyelitis, and the second is the treatment to be pursued. Calculous pyelitis is the name given to an inflammation of the lining of the kidney, the pelvis and its branches or infundibula, dependent upon the presence of a calculus, setting up irritation and inflammation and causing a purulent discharge. It is not a rare disease.

The symptoms which indicate it are, in the first place, the appearance in the urine of pus. This pus is not of the kind that comes from the bladder, that is, mixed with mucus. In cystitis there is nearly always a greater quantity of mucus than pus, but in pyelitis the pus is unmixed with mucus, unless the case is complicated by cystitis, and then the diagnosis is very difficult. When we examine the pus cells with the microscope they have the appearance of having existed for some time. They are not as smooth or unwrinkled as the pus cells of cystitis. With this there is nearly always a considerable proportion of albumen, depending upon the admixture of the liquor sanguinis. There are no tube casts, unless there is associated some inflammation of the substance of the kidney. From time to time there is apt to be a little hemorrhage from sudden congestion or from some unusual exertion causing the stone to scrape against the mucous membrane; but there is usually not so much bleeding as in vesical calculus. The pain is referred to the region of the kidney on one or other side. Pain is caused by deep pressure. There is also another pain very characteristic, that is, after a jar of any kind a sharp, acute pain may be felt in the region of the kidney.

The presence, then, of pus in the urine without much mucus, the occasional admixture of blood which may or may not occur, the absence of morbid vesical symptoms, and, of course, the evidence of the sound, showing that there is neither a stone in the bladder, nor a ribbed bladder, which may occur in an old cystitis, pain re-

ferred to one or other kidney, particularly if excited by deep pressure or sudden exertion, are the symptoms which will lead us to the diagnosis of calculous pyelitis. Particularly so, if they occur in a person with a calculous diathesis, a uric acid or oxalic acid dyspepsia.

In such cases treatment will often do a great deal to relieve the patient's suffering. Quiet, extreme care in diet, the use of mineral waters suitable to the diathesis present, the use of large doses of iron in its diuretic salts and continued counter-irritation will do much to render the patient comfortable.

Occasionally, fragments of stone will be discharged and all the symptoms disappear. In other cases, the symptoms will subside without the calculus being discharged, and you may infer that it has become encapsuled. In very rare cases, the inflammation of the pelvis gives rise to the condition that seems to have followed here, and which I have seen follow in cases like this. That is to say, the inflammation is attended by ulceration, and the connective tissue around the kidney becomes implicated and takes on a suppurative action; or, possibly, the ulcer may perforate the pelvis, the urine and pus may escape into the peritoneal tissue, setting up suppurative inflammation. This abscess may kill the patient before it is diagnosed, or it may discharge in one of several directions; the most common being where this opening is, below the ribs and outside of the sheaf of the erector muscles. When an abscess points in this region, it is to be distinguished from an abscess resulting from caries of the rib, of the vertebræ, and sometimes of the crest of the ilium. This diagnosis is sometimes exceedingly difficult to make, but if we have a history as clear as we have here, I do not see how we could refuse to diagnose the case as a perinephritic abscess.

The question here is to decide whether this is to be left alone, or whether there are any fragments of stone which should be removed. I have been unable to get a probe into this sinus. It appears to be closed at present. I do not think that cutting down on these abscesses seems to do much harm, and certainly dilating this opening to see if there was any calculus, would not; but if we could detect no calculus, this young man's health is so good, and the trouble caused by the abscess so slight, that I do not think we would be justified in performing any serious operation. I shall keep him in the house a little while, but if there is not much discharge I shall leave it alone, and have him return in six months. If there is much discharge, I shall dilate the opening with a sponge tent.

I shall treat him for the pyelitis. I would put him on a good diet, nourishing and digestible, consisting of a moderate quantity of meat once a day, but for the most part of vegetables, milk, the grains and farinaceous articles; care in dressing; the use of a flannel belt around the middle of the trunk, to protect from chills; the avoidance of damp and sudden changes of temperature; a quiet life, some sedentary occupation, total avoidance of any active work, and the internal use of iron in a diuretic form.

One of the most agreeable and useful forms of giving iron is in combination with such a diuretic as acetate of ammonia. This combination has become popular under the name of Bashaw's mixture:—

℞. Tinct. ferri. chloridi, f. ʒ iiss
Acidi acetici diluti, ʒ j
Syr. aurantii corticis,
vel curacoæ, ʒ j
Liq. ammonii acetatis, q.s. ad ʒ v. M.
Sig.—ʒ ss four times a day, in water, after meals.

The dose of the tincture of iron has to be varied for different cases. The tincture of the chloride of iron and the liq. ammon. acetatis may be kept separately and mixed at the moment of taking.

Typhoid Fever.

This is the fever case I showed you last Tuesday, and to the symptomatology of which I devoted the whole hour. I want to give you an opportunity of watching the natural history of typhoid fever, in a well marked case, under the simplest of all treatment.

He came in, I think, on about the fourth day of the disease (the third of May) so that to-day (Saturday) is about the ninth day. You will remember that the symptoms were unmistakably those of typhoid fever. There was an absence of two symptoms which are constantly mentioned, and are frequently present, viz., epistaxis and eruption. There was no eruption when we last saw him.

Let us look to-day. Several red spots at once attract our attention. I feel them, but they are distinctly papular. The eruption of typhoid fever is scarcely at all elevated above the skin; is of a rather pale red or rose color, either round or oval, lenticular, and about a couple of lines long by a line and a half wide. It disappears on pressure but returns immediately on its removal. In other words, it is merely a patch of congestion of the skin with a very trifling effusion in the skin. The spots usually first appear about the epigastric region. They come out about the seventh day. Here are some spots of a paler red, and with these some brownish spots, which are freckles. The little pale spots are worthy of careful study. They were not here two days ago. I press upon one of them; it entirely disappears. It is small, rounded and not raised above the skin. I would not be willing to attach much importance to any of these spots, except the one to which I have called attention. The same mottling of the skin exists that we saw on Tuesday. On the back there are some red spots, which, without being characteristic, are suspicious; but the course of the fever, the distention of the abdomen, the looseness of the bowels, the condition of the mind, the state of the tongue, the condition of the circulation, and the existence of bronchial irritation, render the diagnosis sufficiently certain.

The treatment of this man has been as follows: First, absolute rest, in bed. Now, I consider this a reasonably bad case of typhoid fever, for by the sixth day the temperature was 103.5°, and on the seventh 104°. This is a moderately high temperature, but not at all threatening or alarming. The pulse was 112 and the respira-

tions 32 per minute. He has had no stimulants at all, because there were no exhausting discharges, the nervous symptoms were mild, and the pulse of fair volume.

Secondly, he has had, as his bowels were loose and tongue coated, nothing but milk and water—two parts of skim milk and one part water, probably about fifty per cent. of milk. Of this he received f.℥ vj every two hours—seventy-two ounces of liquid in the twenty-four hours, containing three pints of skim milk.

In order to exert an alterative and sedative effect on the inflamed mucous membrane of the bowel, which is the lesion, the source of the greatest danger and the cause of many of the symptoms of typhoid fever, I gave a pill containing one-sixth of a grain of nitrate of silver and one-eighth of a grain of powdered opium, four times a day.

His temperature has been going steadily down. This morning it was 101.4°, and the pulse 96 per minute. During the second week, instead of this man growing hotter, more restless, dull, with a dry, brown tongue and increased mental disturbance, we see all the symptoms taking a favorable turn. His fever has not been combated by bathing, the cold pack, or other severe measures. We have endeavored to prevent excessive surface irritation, believing, as I do, that this surface irritation is a fruitful cause of the elevated temperature, of a great deal of the nervous disturbance and many of the general symptoms. I think that if we can prevent or modify the development of these local lesions, we shall prevent development of those grave general states that sometimes call for such heroic treatment.

Medical Societies.

STATED MEETING OF THE PHILADELPHIA LARYNGOLOGICAL SOCIETY, NOVEMBER 26, 1880.

Before the meeting was organized Dr. Cohen exhibited a case of prolapse of the laryngeal sack (inversion of the ventricle), and Dr. Bean a case of goitre, which were examined by the members present.

The meeting was then called to order by the President, Dr. Cohen, and after the minutes of the previous meeting had been read, Dr. Harrison Allen read an interesting paper on "Retro-Pharyngeal Abscess in an Adult." This paper was discussed by Drs. Cohen, Turnbull and Allen. In the discussion Dr. Cohen suggested that it would be a good plan to use the aspirator for the removal of pus in such cases and of serous effusions in cases of œdema of the larynx.

Dr Cohen then read a letter from the patient with stenosis of the larynx, which he had exhibited at the last meeting, the letter stating that the case was progressing favorably. The Doctor also reported the history of a case of paralysis of one of the vocal cords and of several of the muscles of the body, of syphilitic origin, which was slowly improving under the iodide; and a case of congenital syphilis, in which the whole of the soft palate had been agglutinated to the pharynx, so that there resulted a complete stenosis of the posterior nares, and in which the uvula was absent.

Dr. Seiler stated that he had seen a similar case, in which, however, the stenosis was not complete.

Dr. Bean then presented a specimen of aneurism of the aorta pressing upon the recurrent laryngeal nerve and upon the trachea, together with a history of the case and a report of the post-mortem examination. The specimen, after examination of the points of interest, together with the case, were then discussed by the members present.

Dr. Cohen then referred to the case of prolapse of the laryngeal sack, reported at the last meeting, and the patient being present, the latter gave a detailed history of his case. He stated that the trouble had been of several months' duration, and was brought on, as he believed, by a severe fit of coughing, but that the protrusion of the mucous membrane was gradually diminishing in size under the influence of an astringent powder blown into the larynx. Having learned to use the laryngoscopic mirror on himself, he was enabled to watch the progress of the trouble. The subject of inversion of the ventricle was then at length discussed, and the rarity of such cases as the present one was dwelt upon. Dr. Cohen proposed to change the name of this affection to "prolapse of the laryngeal sack," inasmuch as it was not the ventricle which became inverted, but the mucous membrane lining the same.

Dr. Cohen then, for Dr. I. Barton, who was absent, reported a case of goitre, in which the treatment had been painting the tumor with iodoform dissolved in collodion, which was followed by marked reduction in the size of the growth. The subject of goitre and of iodized collodion was then discussed by most of the members present.

Dr. Turnbull reported a case of chronic abscess of the tonsil, producing spasmodic cough, induced by the pus running into the larynx; and Dr. Cohen reported a case of spasmodic cough, due to a small erosion in the inter-arytenoid fold. The subject of spasmodic cough was discussed by Drs. Allen, Turnbull, Cohen and Seiler.

After fixing the time and place for the next meeting, the Society, on motion, adjourned.

Carl Seiler, M.D., *Secretary.*

MEDICAL AND SURGICAL SOCIETY OF BALTIMORE.

Cases of Syphilis.

Dr. Cathell. A young lady, perfectly respectable, consulted me about some simple disease, when I noticed that she had a suspicious eruption. I made inquiry as to a sore upon the genitals, which she positively denied. She recollected that about four months ago a young man boarded at her house who was suffering from a sore mouth. Upon one occasion he kissed her, and some weeks after she had a sore on her tongue and enlarged glands under the jaw. I think I am justified in believing that this was the initial lesion of syphilis. I treated her for syphilis and she got well.

Dr. Morris. A young lady consulted me about

a sore mouth, and, as I thought it might be from decayed teeth, I sent her to a dentist for examination. While we were there a young gentleman joined us, and taking me aside, told me that he had contracted the disease from a water closet, and possibly might have infected her by kissing. He subsequently married her, and the offspring were syphilitic.

Dr. Rohe. I have a case now under treatment. A lady was married about three years ago. Six weeks ago I was called to attend her for rheumatism, and found her covered with syphilitic roseola. Since then she has had paralysis, and lately her eyes have become affected. Both she and her husband assure me that they never had any sore, but I do not believe the man.

Dr. Erich. A young lady, aged 16, consulted me about an eruption. The idea of syphilis never occurred to me. I prescribed for her and she went to the country for the summer. When she returned in the fall she was covered with the eruption and seemed to be completely broken down. Then I remembered that I had attended her father for patches in his mouth some months before. She was put under proper treatment and made a good recovery, and seems to be entirely free from the disease.

Dr. Lynch. I attended a young man who, I believe, contracted the initial lesion from a pipe which a sea captain had smoked.

Embolism.

Dr. Rennolds. I attended a lady in confinement, and as it was a tedious labor I used the forceps. She suffered no inconvenience from their use and was doing finely until the eleventh day, when, while she was sitting in her chair, she complained of severe pain in her chest, smothering, etc., and died in a few hours.

Dr. Brinton. I lost a case in precisely the same way. I was called hurriedly to see a lady who was suffering from great dyspnœa, pulseless, and extremities cold. She was perfectly rational. I ordered stimulants but she was dead in half an hour.

Dr. Cathell. A lady went to bed perfectly well, and during the night awoke with similar symptoms. I was hurriedly summoned, but before I arrived she was dead. As she had had an attack of colic a short time before, I, not knowing but that it might be another attack of that kind, took my hypodermic syringe with me. Just before death her respiration was stertorous, and had any morphia been used it might have been thought that the opium contributed to the fatal result.

Dr. Lynch. The cases of sudden death after the use of the hypodermic syringe are caused by the injection of air, and not because the morphia has been injected into an artery or vein.

Multiform Sarcoma.

Dr. Erich. This man, 72 years old, has suffered for about two years. He has about sixty tumors, of different sizes, distributed over his body and limbs. One about the size of an egg is seated on the left temple, and another, the size of a chestnut, at the inner canthus of the right eye; this last one is nearly black in color. About six months ago two tumors, one on the right shoulder and the other just below the inferior angle of the left scapula, were removed by Dr. Gaitley. As a result of the operation fungoid growths occupy the places of the original tumors. He suffers considerable pain and constitutional disturbance. Two tumors have disappeared, as a result, he thinks, of a liniment he was using. The skin is freely movable over the tumors. There is some doubt about the diagnosis, between sarcoma and carcinoma, which only the microscope can decide.

Dr. Coskery. The case is one of considerable doubt. I believe the case to be one of multiple lipoma. Sarcoma being a connective tissue growth is found most frequently in early life, say from twenty-five to thirty years. According to his account the tumors two years ago were the same size they are now. In moving the tumors, one on the thigh is fixed, and many of them move in the skin. The dark color of the one on the eye is due to pigmentation. The fungous masses on the shoulder and below the scapula I believe to be encephaloid cancer, due to the operation for their removal and friction and pressure of the clothing. It was a great mistake to attempt removal of them in a man of his age. On his back, low down, is an undoubted lipoma, and that I believe is the diagnosis—multiple lipoma. The only thing against this is that lipoma is of slow growth and not likely to have attained this size in two years.

Dr. Rohe. The consistence of a tumor is not diagnostic. The large tumor on the back of the man was discovered about three years ago. Multiple lipoma, so multiple as this, is a thing of which I have never heard. The only disease, I think, that this could be mistaken for is fibroma molluscum. A case somewhat similar, except in its beginning, has been described by Duhring. Hebra, Jr., of Vienna, reports a similar case. About fifteen cases have been reported. A case was taken into the Toronto General Hospital, about four years ago. The microscope demonstrated that it was spindle-celled sarcoma.

Dr. Cathell. About eight months ago I saw a case similar to this, with Dr. Dodge. The man was fifty-six years old; had been a soldier for fifteen years; never had syphilis, and seemed to be in good health. He had between fifty and sixty tumors the size of a walnut, and many more much smaller. Ten or twelve of them had fungous growths. None had been removed, but those occupied by the fungous growths had ulcerated spontaneously. We thought it a case of sarcoma.

Dr. Evans. Three years ago I had a case somewhat similar. A man, twenty-six years old, was taken sick, in Chicago, and some weeks after was brought to this city. The tumors were distributed all over the body. He was much debilitated, and suffered from intense headache, and gradually became blind. Drs. Chew and Van Bibber saw the case with me. The diagnosis was lymphadenoma. The man died from brain pressure.

Dr. Bates. I do not think Dr. Evans' case is similar to this. I saw his case several times. It was acute in its character; he had constant pain and there was continued fever. From the beginning of the disease until the man's death did not exceed three months.

Dr. Erich. I am still not convinced that this case is anything else than multiple sarcoma. That a few of the tumors are soft, like lipoma, does not prove that all are. That it is not lipoma I am convinced, by the tumor on the temple; it has a raised bony ridge surrounding it, which does not follow lipoma. That the ulcerated tumors are malignant I think very likely. This man is not debilitated and is able to take good care of himself. All these cases of multiple sarcoma have occurred in old persons. Until a microscopic examination is made we cannot settle the question.

Ophthalmia.

Dr. Scarff. I was attending a case of phlyctenular ophthalmia, and used instillations of calomel. The next time I saw it the case had changed to purulent ophthalmia. The calomel was analyzed, but no corrosive sublimate found in it.

A lady had catarrhal laryngitis, for which I treated her. The next day she came back; the throat was entirely well, and she had ophthalmia, for which I used leeches. The day after the eyes were well and the throat was sore, and for several days this alternation continued.

Syphilis in Natural Development.

Mr. E. S. Brander was Surgeon to a Hospital in the Andaman Islands, and among some other experiences related in the Edinburgh *Medical Journal*, November, gives this account of syphilis:—

Syphilis, in its various forms, was the principal cause of disease among the inmates of the Andamanese Hospital, both numerically and in the gravity of its symptoms.

The study of syphilis among these people was exceptionally interesting, as they may be supposed, prior to its quite recent introduction among them, to have been free from it entirely; and in their case, therefore, it presented the appearance of the effect of the venereal poison acting on a "virgin soil." The conditions met with differed from what I had formerly seen in European hospitals, and also from what is given in the books as the typical appearances.

Such cases as I saw early commenced, among the men, from an ulcerating sore at the edge of the prepuce and extending *outward*. In those cases more advanced the whole *outer* surface of the penis was a succession of chancroid ulcers of various sizes, with some running into each other. In many cases I saw what to me was a new feature, viz., the scrotum and perineum covered with sores of this nature. In one case, I remember that the whole scrotum, most of the perineum, and nearly all the penis, was one continuous mass of ulcerated surface. In the women, the sores on the labia were also of a rapidly spreading kind. As a rule they did not suffer so much from rapid and consecutive ulceration as the men; still there were several cases where nearly the whole extent of the labia on both sides was one continuous ulcerated surface. In addition, there were occasionally sores on the mons veneris and down the thighs. Although these large local sores were clearly due in great measure to want of cleanliness, yet the condylomatous growths so commonly found to result from want of that precaution were comparatively rare. I only remember two cases of the latter, both in men, though it was more frequent among the children congenitally affected. After a varying period from commencement of original sore, the inguinal glands became inflamed, with but little antecedent induration. They rapidly suppurated, and formed large confluent sores. In those cases where the latter were met by treatment they went no further, but in those who had come from a distance, and the sores had advanced, they presented a most extensive appearance, forming great gaping apertures of considerable depth, and involving great loss of tissue. The glands on both sides were nearly always affected, and both men and women seemed to suffer equally in this respect. These were the principal lesions, but were almost always accompanied by one or more of the following: In some there were sores about the nose and mouth, in the latter case commencing as cracks. There were two cases of ulceration of tonsil. I observed, moreover, a marked immunity from ulceration of palate, fauces, larynx, etc., so commonly found in this disease. There was no case of destruction of laryngeal cartilages, etc., or aphonia. In one case commencing ulceration across the bridge of the nose was effectually checked by treatment. In a few cases of mothers suckling children there was ulceration of nipple. The most remarkable feature, however, was a peculiar shallow and spreading ulceration of the skin. I never happened to have a case in hospital when this condition began, but I saw several shortly after, and the appearance then was that of a shallow spreading ulcer—without raised or punched-out-looking edges—and apparently only involving skin tissues, with a tendency to spread indefinitely. The loss of hair was difficult to observe, as they always shave the head. In many cases I found the surface of the scalp covered with an eruption like syphilitic impetigo, going on to syphilitic lepra, but I do not remember any case where the characteristic appearance of syphilitic rupia was seen. There were two cases of syphilitic varioloid, where the eruption was well marked on the face. The spots went through regular stages to maturation, but

never burst externally, the contents being absorbed under treatment, and only a slight desquamation resulting. The syphilitic affections of bones and joints were only found in two cases, and I did not discover any syphilitic nodes on subcutaneous surfaces.

Cases in Mental Therapeutics.

Dr. S. B. Chase reports the following instructive cases, in the Transactions of the Iowa State Medical Society:—

During a stormy night, in the winter of 1863, I was called ten miles to visit a lady supposed to be dying. On reaching the place, I found my patient in terrible convulsions, foaming at the mouth, and gasping for breath. Asking the grief stricken ones to step into an adjoining room, I calmed the storm and soon restored the sufferer in quiet to her friends. The rapidity of the cure satisfied the husband, a somewhat churlish man, of the nature of the malady. As I started homeward he followed me to the door and said, "if my wife has another fit I now know how to cure her." He subsequently assured me of her perfect health. "After you left," said he, "angered that hysterics was the cause of our anxiety and trouble, I returned to her room and sternly upbraided her. She immediately went into a most violent convulsion. Grasping a pail at hand, filled with ice and water, I dashed it upon her. With a shriek she bounded to the ceiling and fell back upon her bed, cured. I lost my patient; the cure was permanent.

Permit me to relate another case. In my boyhood I had the misfortune to break my arm. A lady, well advanced in years, whom we called Aunt Becky, was present. From early life she had suffered from epilepsy, until her mind was much shattered; yet, she was a great charmer. Her invariable custom was slowly to draw the thumb three times each way across the spot she desired to heal, forming a triple cross, and then to kiss the spot.

Great pain continuing in my arm after the surgeon had given it proper attention, Aunt Becky wanted to charm it away. Being faithless, like Thomas, I declined the proffer. A gentleman, some twenty-five years of age, was present, who for ten years had suffered from a bad fever-sore that he had in vain tried to get cured. He said, "Aunt Becky, you may charm my leg, and if you cure it I will give you ten dollars." She was much pleased at the proposition, and immediately began her charming, closing the performance with her customary seal.

The gentleman shortly returned to his home, some distance away, and I did not again see him for years; yet he soon sent Aunt Becky the ten dollars. When I did see him, he expressed great astonishment at the result, as he assured me he had not the slightest faith in the charming at the time, and only consented to the performance because Aunt Becky felt so badly that I could not let her charm my arm. He further said that he did not think of the matter again for weeks after his return home, and not until his leg began to get well. The cure was complete in three months, and has remained permanent. The gentleman is living, a man of prominence, and will corroborate all I say. Could the determination of blood to the part, during the process of charming, have wrought the cure?

The Treatment of Rupture of the Uterus.

Dr. Frommel, Assistant to the Gynæcological Clinique at Berlin, lately communicated a case to the *Zeitschrift für Gebürtshulfe und Gynækologie*, where rupture of the uterus was successfully treated by drainage and antiseptic irrigation of the peritoneum. In the *Centralblatt f. Gynækologie* for August 28th, 1880, he gives at length the histories of two other cases which recovered from the same accident under similar treatment. In the first case the muscular tissue of the uterus was entirely torn through, but the peritoneal covering was intact, though widely separated from the uterus, thus forming a large sac, into which the fœtus had escaped. The woman was put under chloroform, the whole sac thoroughly washed out with a two per cent. solution of carbolic acid, and a large drainage tube passed to the bottom of the cavity. The highest temperature the patient had after the operation was 38° C. (100.4 F.), on the evening of the sixth day, when the whole sac was irrigated through the drainage tube. On the 26th day all discharge from the tube ceased, so it was removed on the 28th, and on the 30th the patient left the hospital. In the second case the child and placenta had both escaped into the peritoneum. The fundus of the uterus was connected with the cervix by a thin band of uterine tissue. The child was turned and extracted, the placenta removed, and the abdominal cavity washed out with a two per cent. solution of carbolic acid, after which a thick drainage tube was carried up as far as possible into the abdomen, and the external end fastened to the posterior commissure by a single stitch. A firm compress was applied to the abdomen, in order to press the fundus down into the pelvis, and an ice-bag was laid over the fundus. The temperature after the operation only once rose as high as 38.5° C. (101.3 F.), and as often as it exceeded 38° C. (100.4° F.) the abdomen was washed out through the tube, under gentle pressure, with at two per cent., solution of carbolic acid. For the first few days the patient got opium, in order to lessen the peristalsis. The tube was removed on the 17th day, the patient was up on the 19th day, and was discharged from hospital, feeling quite recovered, two days afterward. When he published his first case he thought that this treatment was not applicable when the child had escaped into the abdomen, and then he recommended laparotomy, but from the second of the cases now published he has learned that this is not the case, for in it both the child and the placenta had lain in the abdomen for fully six hours.

During the first two days he injects as seldom as possible, in order not to separate the adhesions which have formed; with the same object in view he administers opium. He looks on a temperature of 38° C. (100.4° F.) as an indication for irrigation with a lukewarm two per cent. solution of carbolic acid.

Operation with Thermo-Cautery in Malignant Disease of Labium.

The following case is given in the Glasgow *Medical Journal*, December, 1880:—

Mrs. M'G., aged 69, was admitted 16th August, with a large epithelioma of the right labium. She complained of pain in the right iliac region and of fetid discharge from the tumor.

24th August. To-day, while patient was under the influence of chloroform, Dr. Reid removed the whole of the right labium, by means of the thermo-cautery, going some distance beyond the diseased tissues. No knife or other cutting instrument was used, but the cautery kept at a dull red heat, and it was found to answer the purpose remarkably well. Several vessels required to be ligatured during the operation, but the hemorrhage was only slight. The parts were well syringed with carbolic acid, the lower part of the wound brought together with silver sutures, and carbolic oil dressings applied.

The catheter required to be used only during the first twenty-four hours after the operation. Little or no pain was complained of. On the second day the sutures gave way, and a granulating surface, as large as the palm of the hand, was left: as this healed it gradually contracted, till, on September 21st, when patient left, it was much less than half the original size, and, though still of considerable extent, it had a healthy appearance with a healing margin. No trace of cancerous tissue was observable.

Patient was again seen on 1st of October, when the surface was found to be almost entirely healed, only a minute point being still left. The cicatrix was remarkably small considering the size of the original wound. She expressed herself as free from pain and discomfort, and there was no discharge.

Remarks.—In this case the disease, reaching as it did some way up the vagina, would have been considered beyond the reach of operation with the knife. The patient did not suffer as the result of the operation, and is now free from pain, so that one would not regret having operated even although the disease should recur.

Curious Accumulation of Foreign Bodies in the Stomach.

The following case is reported by Charles L. Dayton, M.D., in the Buffalo *Medical and Surgical Journal*. It demonstrates that in gastric diseases there is great difficulty in forming a correct diagnosis, and also in reaching a reliable prognosis, the problem only yielding a satisfactory solution through a post-mortem examination.

Mr. S., aged 45, residing at Black Rock, for a period of six months had complained of gastric pain with nausea, and other symptoms of indigestion. He presented the appearance of one suffering with scirrhus of the stomach, or aggravated dyspepsia. Failing to secure relief after consulting several physicians, he consented to accompany me, with a view to consult Prof. Austin Flint, Sr., at that time residing in Buffalo. Prof. Flint examined the patient thoroughly, and expressed the opinion that he would ultimately recover. Two days afterward the patient suddenly died. At the autopsy, in the presence of Drs. L. P. Dayton, Tobie and Beaman, the stomach was removed. It contained a tumberful of prune pits; the pyloric orifice was so far occluded by the induration of the surrounding tissues that it admitted only the passage of a small catheter. About three inches from the pyloric orifice the stomach was perforated, probably through the influence of the prunes. His wife stated that he had not eaten prunes in five or six months, and could offer no explanation for his swallowing the pits.

The case is interesting on account of the presence of so large a quantity of foreign substances in the stomach, of the similarity of symptoms to those usually occurring in ulceration and scirrhus, and of the obscurity often attending gastric and intestinal disease, which is cleared up only through the post-mortem examination.

Statistics of Battey's Operation.

In the Chicago *Medical Journal and Examiner*, Nov. 1880, Dr. Jackson quotes from Dr. Engelmann a table showing the result of thirty-six cases in which the operation had been performed in this country and in Europe. Of this number there were 30.5 per cent. of deaths, and 69.5 per cent. of recoveries. Of those who recovered from the operation there were—

Cured	22.8 per cent.
Greatly improved	11.4 "
Somewhat improved	11.4 "
Not improved	17.2 "
Made worse	8.6 "

Dr. Jackson adds: Now, if we add to the number of those who died, 30.5 per cent. the number of those in whom there was no improvement, 17.2 per cent., and those made worse, 8.6 per cent., we have a total of 56.3 per cent. of failures against 43.7 per cent. of successes; for while in ovariotomy performed for the removal of cystic or other disease which is destroying the life of the patient we count it a success when we save that life, a successful case of Battey's operation implies not only the saving of the patient's life, but also the removal or mitigation of her suffering.

Yet, notwithstanding this rather unfavorable showing, I heartily approve of the operation, although I believe it should be confined to a very limited field.

Management of the Cord.

At the close of an article in the New York *Med. Journal* for December, Dr. Lusk writes:—

The outcome of the foregoing observations may fairly be stated as follows:—

1. The cord should not be tied until the child has breathed vigorously a few times. When there is no occasion for haste arising out of the condition of the mother, it is safer to wait until the pulsations of the cord have ceased altogether.

2. Late ligation is not dangerous to the child. From the excess of blood contained in the fœtal portion of the placenta, the child receives into its system only the amount requisite to supply

the needs created by the opening up of the pulmonary circulation.

3. Until further observations have been made, the practice of employing uterine expression previous to tying the cord is questionable.

4. In children born pale and anæmic, suffering at birth from syncope, late ligation furnishes an invaluable means of restoring the equilibrium of the fœtal circulation.

Simple Remedy in Fetid Sweating of the Feet.

Dr. Ortega writes, in the *Gaz. Medic. Algerie* that a workman was afflicted with a continued perspiration of the feet of so fetid an odor that he had become an object of repulsion to those compelled to be in the same room with him. The epidermis of the soles of the feet was found softened, as if macerated, with several ulcerations; but the odor was so disagreeable that careful examination could not then be made. The patient was ordered a simple solution of chloral of one per cent. strength, and was directed to envelope the feet with bandages wetted in it; after two days the fetid odor had disappeared, and after six days the ulcerations were much improved in appearance.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The "Physician's Diary," for 1881, published by William Wood & Co., is one of the latest publications of this character in the mar ket. It contains the usual memoranda at the beginning, and is ruled and paged in the customary manner. Except that the cover has a large and heavy flap, which is somewhat in the way, it would appear well calculated for convenience of use.

——The Board of Health of the State of Alabama have printed a pamphlet (Circular No. 4), containing reports and drafts of bills for the consideration of the Legislature of that State.

These several documents relate, in their order, to the following several subjects, namely:—

1. The supervision of the public health and the collection of vital statistics in the several counties of Alabama.

2. The regulation of the practice of quarantine in Alabama.

3. The increase of accommodations for the insane in Alabama.

4. The protection of the traveling public against accidents resulting from color-blindness and other defects of vision.

5. The nature and treatment of inebriety and the legal management of inebriates.

This plan of presenting the subjects as well to the public at large as to the Legislature, is a judicious one.

——The subject of cancer of the rectum is fully treated in two reprints by Dr. Charles B. Kelsey, of New York city, describing the operation of excision, with its indications and the precautions required in its performance.

BOOK NOTICES.

Photographic Illustrations of Cutaneous Syphilis. By George Henry Fox, A.M., M.D. E. B. Treat, 757 Broadway, New York.

The admirable series of photographic illustrations of cutaneous diseases which Dr. Fox gave to the profession in 1879–80, are, no doubt, known to a large number of our readers. We have now before us the first three numbers of a similar series on cutaneous syphilis, prepared with like fidelity and by the same process.

Dr. Fox tells us that "the study of syphilis is but fairly begun"—an alarming statement in view of the enormous activity of the syphilographers for a century past. He says of his own work that it is the result of the labor of years, and its aim is to furnish a series of life-like representations which shall constitute a panorama of cutaneous syphilis. The colored photographs are accompanied by a text, which presents a practical exposition of the subject, with special reference to points of diagnosis and treatment.

Certainly, the plates in the number before us are exquisite in finish and tone. They are not over-colored and speak directly to the eye.

The work is to be completed in twelve numbers, to contain forty-eight plates in all, and is sold at $2.00 per number.

The Descriptive Atlas of Anatomy. A Representation of the Anatomy of the Human Body. In 92 Royal 4to plates, containing 550 figures. Philadelphia, J. B. Lippincott & Co. London, Smith, Elder & Co. 1880. Cloth.

The engravings in this handsome quarto are upon stone, mostly plain, partly in colors. Without being fine, they are clear and accurate. The names, partly in Latin and partly in English, are engraved upon the parts themselves, whenever this is practicable. This adds vastly to the facility of reference. The arrangement differs a little from that usually adopted, beginning with the bones and ligaments, and proceeding to the muscles, fasciæ, special organs, viscera, circulatory system and nervous system. There is a well-made index, but no table of contents—an omission that should be remedied. The name of the author is not given, but in macroscopical

anatomy it matters little who the author is; his name would add little to the subject. The publishers state, however, that the plates have been carefully revised by competent hands. For a practical, convenient and not expensive anatomical atlas this work can be recommended.

A Practical Treatise on Surgical Diagnosis. By Ambrose L. Ranney, A.M., M.D., etc. Second Edition. New York, Wm. Wood & Co. 8vo. pp. 471.

In the present edition of this work, which has achieved a merited popularity, the author has corrected various errors of statement which appeared in the first edition, and has added a considerable quantity of new matter. He has also, in a measure, dropped the plan of presenting all symptoms in the form of differential tables, and has added new matter, largely as explanatory text.

As we described the plan of the book when referring to the first edition, we need not repeat it here. It will be sufficient to say that the author has bestowed considerable labor on this revision, and has materially added to the value of his treatise.

On the Construction, Organization and General Arrangements of Hospitals for the Insane. With Some Remarks on Insanity and its Treatment. By Thomas L. Kirkbride, M.D., LL.D., etc. Second edition, revised. Philadelphia, J. B. Lippincott & Co., 1880. 1 vol. Cloth. 8vo. pp. 320.

Probably no alienist in the world has enjoyed better advantages for the study of hospital accommodations for the insane than Dr. Kirkbride, and certainly there is none who has made better use of his opportunities. Hence the above work takes the rank of an acknowledged standard, and its perusal is indispensable to every one—physician, legislator, architect or philanthropist—in whose way it comes to form opinions on the subject.

The second edition has been revised, various sections added and new illustrations inserted. It is now the matured record of nearly half a century of observation, during the greater part of which period the author has held the responsible position of physician in chief and superintendent of the Pennsylvania Hospital for the Insane.

A Treatise on Diphtheria. By A. Jacoby, M.D. etc. New York, Wm. Wood & Co., 1880. pp. 252.

This monograph is the result of very extensive study of the disease—"thousands of cases," the author tells us in his preface. The author goes over the ground carefully, giving chapters to the history and etiology of the disease, its manner of infection, incubation and symptoms, its anatomical appearances, diagnosis and prognosis. It is especially full on the subject of treatment, presenting nearly all the real or alleged alleviatives, which have been suggested.

Dr. Jacobi believes diphtheria to be in most cases a constitutional affection, though he distinctly recognizes its purely local character in some cases. He describes it as very contagious, communicable not only by the patient, but by furniture, towels, dwellings, etc. The infectious substance which produces it he inclines to consider a chemical poison rather than a parasitic one. The presence of bacteria, etc., is rather a concomitant than a cause.

Although, as we have said, the book is quite full in its therapeutics, we cannot say that the treatment recommended by the author differs materially from that current among the more intelligent members of the profession; and as this is confessedly unable to deal with severe epidemics, we fear readers will be a little disappointed if they turn to its pages in search of any decided novelty in this respect.

His advice briefly is that every case should be treated individually, on "general principles." He puts alcohol first, as an adjuvant and a remedy. Locally, the main indication is disinfection. Steam is valuable in catarrhal cases; chloride of iron ranks first among antiseptic and astringent agents. Caustics are not highly spoken of; the membrane must not be removed unless nearly detached. Most or all of the specifics brought forward at various times are worthless.

Wood's Ophthalmic Test Types and Color Blindness Tests. Wm. Wood & Co., New York city.

An oblong pasteboard box, ten inches wide and two feet long, contains a series of worsted skeins used for testing the power of discriminating colors, a copy of Prof. Holmgren's "Confusion plate," to illustrate the mistakes of the color blind, a series of test types, very carefully printed, lenses and lens holder, etc. Snellen's types are those which have been followed.

Doubtless, the tests for color blindness will have especial interest in view of the attention which, in recent years, has been directed to this infirmity. The plan of testing it by colored worsteds has proved convenient and sufficiently accurate, and has already been made familiar to the profession by numerous articles. Messrs. Wood & Co. have done well to add to their test type series these more recent methods of examining for defects in the visual apparatus.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A GLANCE AT LAST YEAR'S WORK.

In glancing at the original communications which it has been our privilege to lay before the readers of this journal during the last year, no one can fail to notice how fully they represent the many-sidedness of medical labor and thought.

In the present connection we can but advert cursorily to a limited number, rather to indicate the extent of matter presented than to recapitulate the whole number. In fact, we shall refer to much less than half of the whole.

Especially activity may be noticed among the gynecological workers. The several articles on hæmatoma of the vulva and vaginal thrombus, which were contributed early in the year by Drs. MONTGOMERY, STUART and GAILY, attracted the attention of the editors of Schmidt's *Jahrbuch*, and led to a translation of them and comparison of similar facts from other sources. The mechanical treatment of uterine displacements by Dr. LIMBERMAN (March 6) is an example of the intelligent use of modern means. Passing over several well reported cases of ovariotomy and pelvic tumors, we note the numerous articles on different branches of midwifery. The general doctrine of conservatism in obstetrics was well set forth by Dr. GEORGE HAMILTON (June 19); placenta prævia was discussed by Dr. OLIVER (Oct. 9); puerperal convulsions, by Dr. POPE (Feb. 14); the insanity of lactation, by Dr. BEATES (May 15); the method of delivery by version in the presence of contracted conjugates was defended by Dr. STONE (Feb. 7); a new operation or modification for use in lacerated cervix was described by Dr. HERRICK (Jan. 17). A rare and extraordinary case of recovery after rupture of the uterus was reported by Dr. HOYT (Feb. 14); while a very successful plan for treating the sickness of pregnancy was detailed by Dr. FORWOOD (July 10); and an interesting study of the relations of the menopause was contributed by Dr. ARNOLD (June 5).

The subject of anæsthetics was one which received a new impulse at the beginning of the year, owing to the introduction of bromide of ethyl. We have no hesitation in saying that the most complete articles which appeared anywhere on this agent were in this journal, especially those from the pens of Drs. TURNBULL and SOUWERS and the very able summary by Dr. WILSON (Aug. 7). Anæsthetics in labor found an enthusiastic supporter in Dr. BARR (March 13).

In the domain of medicine proper we might direct especial attention to the lectures of Dr. PEPPER on phthisis, on epilepsy and other diseases, which appeared in the spring and summer. They have excited wide attention. A series of articles on the diseases most frequent in the hot months were presented at the appropriate period; such as Dr. BIGELOW'S papers on the summer diarrhœa of adults (May 1); on insolation (June 19); on the hygiene of infants in summer (May 25); and Dr. ATKINSON'S appropriate lectures on the summer diseases of children (July 17). The remarks of Dr. BLACK on hepatico-cardiac sedatives are very characteristic of his peculiar therapeutics (May 15). The subject of transfusion is illustrated by a well-described case, by Dr. BOERMING (April 14), while the indications for this remedial procedure and the details of carrying it out are fully stated in an article by

Dr. Strout (Sept. 11). A great deal will be found, in both volumes of the year, on the nature and management of diphtheria, and we may mention especially the original communication of Dr. Hill (April 10), and the analysis of seventy-two cases, by Dr. Strout (Nov. 13). Quite noteworthy is the novel therapeutical measure introduced by Dr. Cohen, by the hyperdistention of the pulmonary alveoli (June 12). The special article on dysentery, by Dr. Conner (March 6), on continued malarial fever by Dr. Grant (March 20), and on chyluria, by Dr. Eskridge (April 17), should not be overlooked by those desiring information about these complaints. The important discovery of a new form of disease—catarrhal gland fever—by Dr. Hugo Engel (Dec. 13), will unquestionably attract wide attention.

In the domain of therapeutics, strictly so-called, a good deal has been published about the effects of new remedies. The paper of Dr. Traill Green, on the therapeutic value of the alkaline chlorates, will certainly not have escaped attention (Jan. 17), and Dr. B. Reed's defence of polypharmacy (Jan. 10) is a thoughtful statement of that side of the case.

State medicine has been frequently presented editorially, and a common branch of it, toxicology, is well represented among the communications. The case of injury from the abominable resort of desperate characters, vitriol throwing, reported by Dr. Young, is a striking one (March 13); while Dr. Pepper's lecture on lead poisoning contains several new suggestions (May 22).

We have space but to mention the several interesting studies on statistical and general medicine contributed by Dr. Sozinskey, on the statistics of scarlet fever (January 24), on why there is a period to life (September 4), etc.

Passing to the province of surgery, we must not omit to name the two excellent essays by Dr. Vance, the one on the painless cure of internal hemorrhoids (May 8), the other on obscure diseases of the rectum (Aug. 14). On the same branch are Dr. Byrd's able description of the method of the extirpation of the rectum without cutting the sphincter ani muscle (Nov. 11), and Dr. Roberts on early excision in cases of rectal cancer (Oct. 23). The description of Heaton's method for the radical cure of hernia, by Dr. Warren, remains as the most complete which has yet appeared (March 27). Dr. Weir's notes on gonorrhœa (April 24), and Dr. Boyland's companion piece on inflammations of the urethral mucous membrane (Sept. 18) will repay reading again. Dr. Wight's articles on fractures (Aug. 14, Sept. 25) are particularly instructive, and the same should be said of that of Dr. Roberts, on head injuries (Sept. 4).

The specialties of diseases of the eye and ear have received a full share of attention for a journal which defines its chief aim to be to supply the wants of the general practitioner. The audiphone and dentaphone were described, we believe, in the Reporter, in advance of any other medical journal; and the articles of Dr. Charles Turnbull early assigned to these instruments their true place. In ophthalmic surgery we merely name the contributions of Dr. Keyser (July 10); of Dr. Schell (July 17); of Dr. Landesberg (May 1, Sept. 18); of Dr. Oliver (Sept. 4); of Dr. Hill (April 3), to show that both the immediate and the sympathetic affections of this important organ have not been neglected.

Here we close our review, not from lack of matter, but because all we set out to do was to indicate how various and how rich is the material in the columns of an active journal. Were the survey extended to the other departments, to the clinics, periscope, notes and correspondence, the results would probably cause surprise at the extent and variety of the information the two volumes contain; yet they show but a part of the medical conquests of the year; so vigorous and progressive is the science we cultivate.

For the year now commencing we have made arrangements to have a still wider scope of contributions. Gentlemen of distinction in several special branches have expressed their willingness to send us the results of their current studies; several active medical societies will be represented which have not hitherto appeared in our columns; translations of a series of clinical lectures from some of the most eminent Parisian professors have been engaged; and in a variety of ways the survey of the field of medical science will be widened.

Notes and Comments.

Melanotic Sarcoma—Cerebral Tumor of Same Nature—Aphasia.

M. Ozenne reports this interesting case in *Le Progrès Medical*, No. 41, 1880: A woman of twenty-seven was brought to La Pitié Hospital, in a comatose state. All the internal organs seemed normal; the temperature but slightly elevated; pupils dilated and insensible to the light.

After a few days the coma passed away, but it was found impossible to obtain any reasonable response to questions concerning her condition previous to the attack. A small tumor was found developed in the skin over the first metatarsal bone of the right foot; this tumor was mobile, without connection with the bone, but was the seat of a fungous, blackish ulceration, with indurated borders; proceeding from it up the leg small nodules or roundish masses were found, in the course of the lymphatics, as far as the groin. Several similar nodules were found over the breast. The examination of the eye and the orbit revealed no disease; the internal organs appeared normal; the sphincter muscles alone were paralyzed; micturition and defecation were involuntary; the pulse and temperature were normal, but there was complete aphasia. At the post mortem, the heart was found to contain in its walls a number of small nodules resembling those in the skin of the breast, the endocardium being particularly affected; the other internal, thoracic and abdominal organs were normal. On the surface of the brain a number of similar small nodules were found; the cavity of the left ventricle was dilated by a tumor as large as an egg, soft, black, giving a dark liquid on pressure; in the cerebellum, also, a few nodules. These tumors, on histological examination, presented the characters of melanotic sarcoma.

When, as in this case, the generalization of the disease did not affect the eye or the orbit, the diagnosis of melanotic sarcoma may be affirmed, for the eye is not secondarily affected in this form of sarcoma (Cornil and Trasbot) while in the same form of carcinoma the eye and orbit are apt to be invaded. The brain is not generally attacked, unless there is primitive melanotic sarcoma of the eye or orbit, and this case was exceptional. The situation of the tumor in the ventricle, and the absence of paralysis, convulsions and contracture would seem to confirm the experimental researches of M. Cossy, who affirmed "that effusions into the ventricles, whether serous, or sanguinolent, or purulent, if not in great quantity, and particularly if slowly effused, were not accompanied by convulsive phenomena." The aphasia was explained by the compression exercised by the ventricular tumor on the convolution of Broca (third left frontal).

The Limited Effects of Sanitation.

A serious doubt was cast on the effects of sanitary work, by Dr. John Syer Bristowe, in a recent address as President of the Society of Medical Officers of Health. His words were:—

If we look to the remarkable influence which simple variations of temperature and peculiarities of season exert on the mortuary returns, in respect both of the numbers of deaths and the character of the fatal diseases, and compare therewith the comparatively small effect on the death-rate of even one of the most fatal of the zymotic diseases, or with the insignificant influence of deaths from enteric fever, diphtheria, pyæmia, puerperal fever, and other affections over which sanitary science is supposed to exert a specially valuable influence, we can scarcely avoid, I think, seeing that, on similar grounds, the deaths saved directly by the sanitary labors in which we are engaged must, under any circumstances, be so few annually as to produce no distinct and unmistakable effect on the mortuary rates. I trust, gentlemen, that it will be distinctly understood that I do not deny that valuable (and invaluable) lives are saved by our labors; still less that health is promoted and human happiness by so much increased in virtue of them. I simply venture to urge that these results are not yet—at any rate, to my mind—distinctly manifested in the death-rates; and that it behooves us not at present to boast of results which we cannot prove to have taken place, but to investigate and labor at the death-rates and death-returns in a teachable and hopeful spirit, with the object of discovering in them, if possible, the evidences which, I trust, they contain of the success of our labors in promoting longevity.

The Antiseptic Treatment of Empyema.

This valuable step in advance should be known to all physicians. Not long since, at a meeting of the Manchester, England, Medical Society, Dr. Ashby related three cases, two of the patients being shown at the meeting. The ages of the patients were two and a half, five and seven years, respectively; all three had a history of five to seven weeks' illness. The treatment consisted

in opening the chest under the spray, after the fashion of Hilton's method of opening abscesses, that is, making a free incision through the skin of the ninth intercostal space, just in front of the angle of the rib, and pushing a pair of dressing forceps through the muscles into the pleural cavity, thus avoiding all chance of wounding the diaphragm. Then, about half an inch of the ninth rib was excised by a pair of bone forceps, and a short drainage tube inserted. The dressings were renewed daily for the first week, but by the end of the first month the discharge had become scanty, and dressing every third or fourth day was sufficient. In two of the cases the discharge had ceased and the wound healed by the end of two months; and in the third in two months and a half. One of the children weighed twenty-six pounds on June 27th, when operated upon, and thirty-one pounds ten ounces on August 27th, when the wound had healed. In October, three months after the operation, all three were well; there was no reopening of the wounds.

Vesical Spasms in Young Children.

We learn from the *Journal de Medécine et Chir. Prat.*, that MM. D'Espine and Picot devote an interesting chapter to this affection, in the second edition of their "Manuel des Maladies de l'Enfancè." They consider that this form of spasm is of more frequent occurrence than is generally supposed. It is sometimes seen in the new-born child, and is due, in them, to the accumulation in the bladder of urates of ammonia, which are of frequent formation in the kidney at this period of life. But any malady, intestinal catarrhs or lung troubles, or other disease accompanied by high fever and consequent concentration of the urine, may induce this spasm, as also the presence in the bladder of a calculus, etc.

In somewhat older children, not properly protected with drawers, this trouble is apt to recur at intervals. In very young children, the sudden suppression of the urine, accompanied by agitation, should lead to a suspieion of vesical spasm. In older children, frequent desire to urinate will be expressed, but such pain will be induced in attempting to pass water that the child will dread the attempt, and all trouble will cease on the spontaneous or instrumental evacuation of the urine.

In very young children, sweetened emollient drinks may be given, to aid in the elimination of the urates. For older children, warm cataplasms should be placed over the lower part of the abdomen, the child placed in a warm bath and encouraged to urinate therein, an ointment containing belladona applied, and where the spasms recur, flannel drawers should be worn. Bokai recommends, also, suppositories and enemata containing small doses of opium.

Blistering in Anuria.

M. Lombard reports, in *Le Concours Médical*, No. 42, 1880, a case supervening on the abuse of drastic purges and diuretics for three months, in a case of heart disease, accompanied by œdema of the limbs, etc.

At first the urine was voided with much pain and contained blood; then, after two days, complete anuria, with much pain in the glans. Belladonna frictions over lumbar regions, narcotics internally and in enemata, were tried, but without benefit, neither lessening the pain, nor giving any relief, and after three days, when there was less pain, a blister was placed on the lumbar region; the next day a small quantity of urine was voided without pain, and the following day a much larger amount was secreted, and the amount voided continued to increase, and without pain in the passage. The author considered the anuria to have been induced by an attack of acute nephritis, brought on by the use of irritating remedies.

Tabes Dorsalis Cured by Nerve Stretching.

Dr. Langenbeck reports, in the *Berlin. Wochenschrift*, a case of tabes dorsalis, in which nerve-stretching, conducted under antiseptic precautions, resulted in a complete cure. The left sciatic was first operated upon; the motor and sensory paralysis following disappeared in a few days. Twelve days subsequently the right sciatic and both crural nerves were stretched, and with the same results. The feebleness which marked the first efforts at locomotion soon passed off, and the ataxic symptoms disappeared.

Lactic Acid in Vesical Catarrh.

Dr. Deecke, in *L'Union Méd. du Canada*, considers, after extensive experiment, that of the acids lactic acid gives the best results in this affection. He gives from fifteen to twenty grains, ter in die. After forty grains have been taken its presence can be detected in the urine. He asserts that it checks ammoniacal decomposition in the urine, that it dissolves the excess of saline constituents and destroys the microscopic fungi often developed in such urine.

Special Reports.

REPORT ON THERAPEUTICAL AGENTS.

Editorial Introduction.

It is proposed to lay before the readers of this journal, from time to time, reports on the various branches and specialties of medical science, drawn up by writers who devote particular attention to the subject on which they write. These reports will contain, not merely abstracts of recent developments in the field to which they are confined, but also an estimate of the value of discoveries and novelties, by the compilers. It is not sufficient to describe alleged improvements in the art of medicine; sharp criticism of the basis of such claims is imperatively demanded; and it is this which the editor of this journal wishes to introduce into the series of reports of which this is the first. Others of the series will follow, from time to time, as materials present themselves.

It will greatly aid the accuracy and worth of these reports if readers would send us a statement of their *failures* with new instruments and new remedies. Their names will not be published, but the facts will be recorded for the benefit of the profession. There are so many journals published for the purpose of reporting good results only, and so many physicians careful to write only their lucky hits, that this journal announces itself as particularly desirous of hearing the other side, the failures and the pieces of bad luck. We may confidentially mention that we suspect they are not in the large minority. We repeat that neither names nor locality will be stated in the use of these communications, but both are required, so as to authenticate the statements made.

REPORT I.—ON THERAPEUTICAL AGENTS.

Pilocarpin.

This, as is well known, is an alkaloid obtained from the leaves of jaborandi. It has already been referred to in the Reporter as exhibited in *uræmia* and *albuminuria* (July 3d, 1880). Dr. L. Von Hoffer, of Austria, has seen marked improvement in *diabetes* from hypodermic injection of one-third of a grain of the alkaloid.

Prof. Pick, of Prague, has given one-sixth of a grain of the muriate, once or twice a day, an hour after eating, and found it of some benefit in *prurigo*, *pruritus* and *chronic urticaria*; of little or none in *eczema* and *psoriasis*. A singular fact he noticed was its remarkable *effect on the hair*. It hastens recovery in alopecia areata, and acts even more favorably on seborrhœa; indeed, in most cases he says that continued use of pilocarpin exerted an important influence on the oiliness of the hair and on its growth. The skin becomes softer, more pliant and satiny; comedos and papules of lichen pilaris can be more easily pressed out or got rid of, the scurfiness of the scalp becomes less or disappears, the hair is less brittle, the new growth of lanugo hairs changes more rapidly into dense, properly pigmented ones. Under employment of the drug for months the general condition of the patient was not impaired; indeed, the appetite improved, and he was better nourished (*Vierteljahrschift für Dermatologie*, I. 1880).

The drug also exerts a stimulating influence on the retina. Dr. Mecklenburg (*Berlin. Klin. Woch.*, No. 44, 1080) gives this case:—

A strong and healthy male prisoner, twenty-four years old, who had never previously suffered with his eyes, suddenly became night blind; as soon as dusk set in he could see nothing. It was a case of hemarolopia. The pupils were greatly enlarged, but nothing else abnormal about the eyes.

After the usual means had been tried, Dr. M. injected subcutaneously—

℞.	Pilocarpin muriat.,	0.1
	Aquæ destil.,	5.0

The improvement was immediate, and after the third injection the patient was well.

In Berlin it has also been tried in *syphilis*, when it has reached its constitutional stage, principally by Dr. Lewin, of La Charité Hospital. The following extract from the London *Medical Press and Circular* gives its advantages and disadvantages thus—

In the course of three years and a half he has treated thirty-two patients. Seventy-eight per cent. of the patients were cured. Of seven cases two were of serous form, and had resisted energetic mercurial treatment; the cure was incomplete, and it was necessary to have recourse to injections of corrosive sublimate to complete it. In five other cases the treatment had to be suspended on account of intercurrent complications (endocarditis, hæmoptysis, collapse).

The mean duration of the treatment was eighty-four days. The dose injected each time was usually fifteen milligrams. The cure would be shorter if patients would have daily injections; but as soon as amendment of the symptoms begins they require less and less frequent applications of the remedy.

Pilocarpin seems to prevent relapses with greater surety than mercury or vegetable depuratives. But in respect to facility of application, certainty of result and rapidity of cure, this medication is inferior to injections of corrosive sublimate, and often leaves behind it extreme sensibility to the influences of temperature, which obliges patients, after the cure, to keep their room for some time, for fear of arthritic and rheumatic troubles.

In *diphtheria* it was editorially recommended in the Reporter (vol. xliii, pp. 524, 540), on the strength of the assertions of Dr. Guttman, of Berlin. His prescriptions were, however, not quoted. They are as follows, he combining pepsin with the alkaloid, in order to combat the gastric catarrh present:—

℞. Pilocarpin muriat., gm. 0.02—0.04
Pepsin, gm. 0.6 —0.8
Acidi hydrochlor., gtt.ij
Aquæ dest., gm. 80.0 M.

Sig.—A teaspoonful hourly, for children.

For adults—

℞. Pilocarpin muriat., gm. 0.03—0.05
Pepsin, gm. 2.0
Acidi hydrochlor., gtt.iij
Aquæ dest., gm.240.0 M.

Sig.—Hourly, a tablespoonful.

Dr. Rothe, of Altenburg, says (*Med. Cent. Zeitung*, Nov. 6th) that four years ago he tried jaborandi in two cases, but both died, and he renounced the experiment. This throws some doubt on the value of Guttman's discovery.

The price of pilocarpin is high; it sells in the eastern cities at thirty-five cents per grain, which makes it almost prohibitive in many cases.

Homatropin and its Allies.

The chemists Kraut and Lossen found that atropin may be split up into *tropin* and *tropic acid*, and last year Ladenburg succeeded in reforming atropin from these two constituents. By treating the different salts of tropin with dilute hydrochloric acid, a class of alkaloids may be artificially produced, to which Ladenburg has given the generic name of *tropeïns;* homatropin is one of the alkaloids so obtained. Homatropin retards the heart's action; subcutaneously injected, in man, in doses of $\frac{1}{50}$ to $\frac{1}{30}$ of a grain, it slows the heart by 21 beats per minute, on an average. It antagonizes muscaria. It antagonizes pilocarpin also, arresting the sweating excited by that drug within ten minutes; atropin acts similarly, and more promptly.

The *Practitioner*, October, 1880, says:—

Dr. W. Murrell has used homatropin (hydrobromate), for the night sweats of phthisis, giving it hypodermically in doses of $\frac{1}{60}$ to $\frac{1}{10}$ of a grain; $\frac{1}{6}$ of a grain produced unpleasant effects, such as dizziness, a sickly sensation, and great disturbance of vision; the effective dose was about $\frac{1}{20}$ of a grain. Dr. Murrell has given fifty of these hypodermic injections of homatropin to sixteen patients, and concludes that, although the drug has undoubtedly the power of checking the hypersecretion, the results were not sufficiently satisfactory to justify the belief that it would rank high as a remedy for this distressing symptom. It is decidedly inferior to atropin, Dover's powder, picrotoxine, and other means at our disposal.

The price of homatropin in Philadelphia, at present, is $1.25 *per grain*—so high that it is out of reach as a remedy.

Gaultheria Procumbens.

This wintergreen is chiefly used in this country to impart an agreeable flavor. But Dr. Perier, of Hôpital St. Antoine, uses it as an antiseptic, as follows:—

℞. Essentiæ gaultheriæ, 6 grams
Tinct. quillayæ, 30 grams
Aquæ, 1 litre.

This forms an excellent fluid for injecting into the bladder, for washing wounds, and for some simple dressings. He uses it especially in the treatment of purulent cystitis. It is a powerful antiseptic, of a penetrating but not disagreeable odor and non-irritant. Though its price is high, this does not form a bar to its use, as it is given in very small doses. The essence of winter green is procured from the *gaultheria procumbens*, a North American shrub. Chemically, the essence is called salicylate of methylene, or methylsalicylic ether; it is only slightly soluble in water.

Correspondence.

Aspergillus Nigricans.

Ed. Med. and Surg. Reporter:—

On our return from Europe, and during the voyage on the Atlantic, my wife complained of an uneasiness and a sensation of fullness in her right ear, more especially when exposed to a cool draft of air (such as a hurricane-deck promenade). However, I took no notice of it, as her suffering was of such transitory character. But later, after spending several days in New York, and on leaving for our home in the South (Texas), and ere we had sped half the distance to our native land, over the beautiful hills and fertile valleys of New York, and along the line of the "Erie Road," the severity of the pain increased to that intensity that it remained unmitigated for twenty-four hours, although under the influence of an anodyne. I naturally inferred that it was a case of acute myringitis, reaching suppuration, as after relief came the discharge was the most prominent symptom, attended with impairment in hearing, vertigo, pain in the ears, and *tinnitus aurium*.

On my arrival home, on the 28th of September, 1880, I made a specula examination, which revealed on first inspection, without ablution, a deplorable condition (the membrane being partly obscured by pus); but after syringing the ear out well with tepid saline water, I saw at once that I was dealing with *aspergillus*, which was firmly intact; but repeating the warm saline injections, and now with gentle persuasion by the aid of a delicate pair of forceps, I was enabled to remove it entire, and in a perfect cast of the external

ear, leaving a beautiful expose of the tympanum and external ear, which presented itself as follows: the tympanum being perforated at its anterior and inferior quadrant—the whole surface of the external ear presented a glazed red appearance—and on reëxamination, soon after the removal of the aspergillus, was seen deposited a whitish exudation, or pseudo-membrane, which was reproduced, in twenty-four hours, to its former size. I again removed it, and now taking the precaution to use the instillation a little stronger, which was composed of zinc, carbolic acid, glycerine and alcohol, in the interim using the injection of the "sulphate wash," also occasionally using insufflation of iodoform, which is reduced to "palpable powder" by the action of alcohol. The Eustachian tube opened sluggishly, and was kept open by the aid of a Politzer air bag. I had no difficulty in the repeated removal of this obstinate growth, but to no purpose; just as sure as I removed it, just so certain was it to return.

I will state here, however, that after its second removal its reproduction was slighter, until a mere abortion was observed (a very thin coat of membrane showing the impression of the perforated drum, the thickness of tissue paper). In the meantime I had sent the specimen to Dr. Knapp, of New York, for microscopical examination, and he replies:—

New York, November 8th.—Dear Doctor, Your specimen is aspergillus in its *finest form*, and has given us great pleasure. You will cure it quickly by using—

℞.	Argent. nit.,	gr.v
	Glycerinæ,	
	Alcoholis,	āā ʒj.

by instillation immediately after removing the pseudo-membrane. Yours truly, H. Knapp.

Another very interesting feature in this case was that I removed two small bodies lying just underneath the skin, and being ulcerated through, situated near the "external meatus auditorius;" these were about the size of duck shot, and resembled in character very much the aspergillus, presenting a darkish appearance, as though sprinkled over by charcoal dust. I believe this affection is almost as rare as cysticercus in the eye. Dr. Moyer reports a case in 1844; Pocine, one in 1851; Schwartze, one in 1865; Roosa, two in 1870; Green, three in 1871; and Robert Wrenden, St. Petersburg, eight, making in all fourteen up to 1872. Since then we have reports from Drs. Knapp, Bush, Burwill, Spencer, and others of our own country. E. W. Rush, M.D.

Paris, Texas, Nov. 18th, 1880.

A Tough Case.

Ed. Med. and Surg. Reporter:—

During the summer of 1878, while visiting a patient in the family of Mr. W., I was requested to prescribe for a daughter of W., and receiving a hint that it was some catamenial trouble, I called the mother of the young lady aside and gathered from her the following history:—

Miss M. W., age twenty-two years, American, tall, thin, and quite pallid; antecedents fair. At the usual period of puberty the menstrual nisus began to develop, but no flow followed; the mother became anxious for her daughter's welfare and called in the family physician, who used, as I am informed, almost all known remedies adapted to such pathological conditions as presented at the time, without any apparent benefit. In the meantime Miss W. arrived at the age of seventeen years, when, without any unusual premonitory symptoms there was a *slight show*, which lasted for an hour or two, and then disappeared, to return at irregular intervals up to the above date. Present condition very anæmic; cold extremities; pain in the lumbar region, always increased by lifting; smothering sensations accompanied by palpitation when lying down; the above conditions are always worse for a time after each menstrual nisus, whether or not there is any flow. When there is any *show* the discharge is in small clots, which pass from the uterus unaccompanied by pain or any particular discomfort.

I diagnosed (and an examination verified my opinion) prolapsus uteri as the prime factor in causing the major part of ill feelings. This condition I proposed to effectually relieve, which I did with one of Staufer's invaluable uterine supporters. The scanty menstruation I believed depended upon the impoverished condition of the blood, and I assured the anxious parents as I had relieved the prolapsus so nicely, I could accomplish a cure in the other trouble, and that my measures would consist of: 1st, Sanitation; 2d, Alimentation; 3d, Medication. My directions were followed to a letter, but after two years strenous effort in sanitation, alimentation, and medication—and of the latter I used iron in almost all forms, singly and in combination with nux vom., arsenic, aloes, myrrh, etc., etc., *ad infinitum*—all have failed, and my patient is no better, as far as the menstrual trouble is concerned, than she was two years ago.

But now comes to me a very peculiar phenomena in this case: my patient, with the mother, have but recently informed me of the *fact* that at no time will the menstrual flow come on, or stay on, if the feet and hands happen to get warm; or if a perspiration comes on the flow will immediately cease, and will come on again when the extremities and body go back to their normal condition.

I want light on this, to me, very interesting case. All suggestions in the way of treatment, or otherwise, thankfully received from my medical brethren. W. W. Fierce, M.D.

Wilksville, Ohio, Nov. 20th, 1880.

Dermic Dressing in Variola.

Ed. Med. and Surg. Reporter:—

Pulverized talc, or steatite, is a most elegant dressing for moist skin affections of both infants and adults. For ten years it has, in my hands, proved a useful medicament and choice vehicle, topically employed. During the last three months some thirty cases of smallpox have come under the writer's observation, in which steatite has answered a most desirable object. Sweet oil and glycerine, mixed in equal parts, is applied

for two or three days to the heated skin and forming pustules. As soon as the pustules are matured, or turn yellow, the steatite is applied over the face, neck and hands, mixed in water, in the form of paste or whitewash; repeated as often as it falls off or is rubbed off.

It is an energetic absorbent, a deodorizer, overcoming that evil smell peculiar to variola. It controls the "itchy burning" of the surface. It prevents the second formation of crust over the pustules, and thereby renders the pits in the skin less distinct. To the touch it is soft as velvet and as adherent as bronze. For the above named needs it seems to be the Geodine of earths.

A. S. Hudson, M.D.

Stockton, Cal., Dec. 7th, 1880.

News and Miscellany.

Notes from the University of Pennsylvania.

We are informed by Dr. Pepper, chairman of the Finance Committee of the University Hospital, that Mr. Henry C. Gibson has offered to erect a new wing for incurables, in connection with the University Hospital, at a cost of about $50,000.

The plans are being drawn by Mr. Hewitt, the well known architect, and will be submitted to the examination of a committee of experts in hospital construction, so as to insure the highest degree of perfection in all details. This munificent gift assures the immediate completion of this department, the need of which has been so urgently felt. It will have accommodations for about one hundred beds, and will thus afford an incalculable amount of relief to poor sufferers from chronic diseases, who cannot afford suitable hospital treatment elsewhere.

The proceedings of the charity ball, to be given in behalf of this new department of the University Hospital, will now be devoted to its endowment fund. Further contributions toward the endowment fund are, however, greatly needed, since it will require the interest on an investment of $500,000 to support the entire number of free beds (100) that will be contained in the new building. This extension was needed because the present accommodations of the University Hospital do not admit of the thorough classification of the cases, which will be practicable as soon as the new wing is occupied. It is designed that it shall be ready for patients by October 1st, 1881. It is to be earnestly hoped that the example thus set by Mr. Gibson, of giving during his lifetime a large sum of money to accomplish a definite and greatly needed object, will soon be followed by others. All taxes entailed upon charitable purposes are thus avoided, the exact accomplishment of the donor's wish and intention are secured, and great enterprises are strengthened at most critical moments in the most conclusive manner.

We note with pleasure, in this connection, the recent munificent gift of Mr. Temple to the Academy of Fine Arts, and of Mr. J. W. Williamson to various institutions, and of Mr. John Welsh in founding the professorship in the University, which bears his honored name; but there is still ample opportunity, and most urgent need for similar large gifts, especially to this latter institution, the University of Pennsylvania, to supply the advantages which are imperatively necessary for its proper expansion and full prosperity.

A library building of spacious proportions, to contain the large collection of the University, is greatly needed, but even more important is the need for the endowment of professorships and scholarships, which would encourage science and learning and relieve the financial needs of this great educational institution.

The Increase of the Pellagra in Italy.

Our Consul at Milan reports to the National Board of Health *Bulletin* that, under the direction of the Italian Society of Hygiene, aided by the government, a careful investigation was made, in 1879, into the causes of the steady and alarming increase of *pellagra*, a disease afflicting the laboring classes. The disease attacks the skin, brain and muscles, destroying the powers of the body and transmitting its germs to the offspring. The report of the committee of investigation as to the extent and causes of the disease is now published.

There are over 20,000 cases in Lombardy. In some districts from ten to fifteen per cent. of the population are afflicted.

The effects of the disease are shown in the military levies of the years 1878 and 1879, when in the province of Lombardy twenty per cent. were rejected for physical incapacity, while in the provinces where *pellagra* does not exist there were but ten per cent. rejected.

In the *pellagra* districts the laborers live on Indian corn or maize, using no meat and few vegetables. The maize is crudely prepared in the form known as *polenta*, being rarely well cooked or salted. This restricted diet is the result of poverty, and is the generally assigned cause of the disease; their houses are also poor.

To lessen the evils, the following measures are proposed: The amelioration of the condition of the laborers; the improvement of their habitations; diffusion of hygienic precepts; a variety of food; use of wine; prohibition of marriage among the afflicted; the letting by landed proprietors of garden plots to laborers; the propagation of the rabbit, as affording cheap, fresh food; the purification of drinking water; and an increase of wages.

While the above recommendations are good, they do not aim at the root of the evil, which is *over-population*. Measures for the encouragement of emigration from the crowded districts can alone relieve their agricultural population.

Scarlet Fever in Western Pennsylvania.

The Pittsburg *Evening Telegram*, December 24th, says: This will be a sad and mournful Christmas for the little town of Houtzdale, Clearfield Co., in this State. That fearful scourge, scarlet fever, is rapidly thinning and desolating every household in the place. Eighteen children died yesterday from this terrible disease, and this

morning many new cases are reported. It is but a few days since the first case was made known, and already thirty deaths have resulted from the fatal fever. Physicians have been summoned from all the neighboring towns, as the few doctors here were all overworked and could not possibly attend to all the demands made upon them. There is scarcely a family in the town that is not plunged into deepest grief over the untimely taking away of their beloved little pets—scarcely a hearthstone in the place that has not been desolated.

Attack of Trichinosis.

What we so recently urged in this journal about the unsuspected presence of trichinosis among us is corroborated by the following fact:—

In Franklin township, Erie Co., Pa., six members of a family of seven have died within a few weeks, as supposed, from typhoid fever. Last week another family of four was reported as in a dying condition, with similar symptoms. Dr. Germer, the Health Officer of Erie, having heard that these families had butchered before seizure, went out to investigate, and upon examining the pork eaten by the families, the microscope revealed swarms of trichinæ, leaving no doubt that death resulted from trichinosis. A county commission is called for.

Items.

—Dr. Ryle, the new Bishop of Liverpool, must be a man of infinite tact. Being called on recently to address an assembly of medical men, he remarked: "I am not ashamed to say I have a son a doctor." The audience, it is said, hardly seemed to appreciate the compliment.

—The medical students at the University of Pennsylvania not long since came into collision with the academics. From all accounts it would have been merely a friendly tussle had not the police rushed in and put a more serious aspect on the fray. Several were wounded on both sides.

—One of the curiosities reported by the present census is an Alabama giant, only twelve years of age, who weighs 380 pounds and is six feet in height, while both his parents are of medium size. Fulton county, Georgia, furnishes, in the person of Miss Lavinia Cobb, a lady who has seen her five score years and ten. Missouri has a veteran who was born in 1776.

—Fourteen Chinese lepers were shipped from San Francisco back to their native country last month. Each one was provided with a small sum of money for his immediate necessities on reaching Hong Kong. Chinese Consul Bee has telegraphed to the Chinese authorities, and they will be taken direct from the steamer to the Leper Hospital, at Canton. It is believed all the lepers in the city are included in this shipment. The lepers presented a hideous appearance, and their countrymen on board the steamer refused to go near them.

Obituary Notices.

—Dr. Edward H. Dixon died last month, aged about seventy-two years. He was editor of the *Scalpel*, a well-known semi-medical journal, previous to the war of the rebellion.

—Dr. William Herbst, of Reading, Pa., died in that city on Thursday, December 16th, aged seventy-six, of an affection of the lungs. He was one of the first students of the Jefferson Medical College, of Philadelphia, at a time when the class contained only eighteen members.

QUERIES AND REPLIES.

MR. EDITOR:—Can you give me the formula for "London Paste," as referred to by Mackenzie in his work on diseases of throat?

Iowa. O. S. K.

Ans.—Full directions for making and applying London paste will be found in Napheys' *Surgical Therapeutics*, p. 292. They are minute and too long to quote here.

MR. EDITOR:—Do you think the tricycle can be utilized by the busy practitioner in this country, and what is the probable cost?

Tennessee. T. E. B.

Ans.—They cost about $20—$30. They can only be used with advantage on well made, hard roads, of moderate grade, hence they would not suit many American physicians.

Dr. S. P. of Mich.—Vanilla was used by the ancient Aztecs as a condiment, before the arrival of the Spaniards.

Viator.—The reputation of the Bermuda Islands as a health resort is probably over-estimated. We have never seen permanent benefit in consumptive cases from a winter spent there.

Dr. S. K. A. of Ind.—We can procure and send you the books. Remit retail price and they will be mailed you postpaid.

MARRIAGES.

DEACON—COLLINS.—At Friends' Meeting House, Frankford, this city, on the 12th Month 2d, 1880, Benjamin H. Deacon, M.D., and Sarah A. Collins, daughter of Robert R. Levick.

MOELLER—NEIDLINGER.— n Wednesday, Dec. 15, 1880, at the residence of the bride's sister, by Bishop A. A. Reinke, of the First Moravian Church, Henry Moeller, M.D., and Josephine H. Neidlinger, all of this city.

DEATHS.

CLEMENTS.—In New York City, on the 13th inst., Nelson Clements, Jr., M.D., in the 25th year of his age, son of Nelson and Emily Clements.

DE TEJADA.—In New York City, on Sunday, December 12th, at two o'clock P.M., at his late residence, No. 54 West 35th street, Antonio G. De Tejada, M.D.

FRANKLIN.—At Diona, Coles Co., Ills., on December 19th, 1880, of phthisis, Leah Franklin, wife of Dr. John W. Franklin, and daughter of A. Dowden, of Diona, Ill., aged twenty-eight years, ten months and twenty-four days.

GALLAHER.—At Bristol, Pennsylvania, December 10th, William D. Gallaher, M.D., in the 78th year of his age, formerly of Philadelphia.

POPE.—Of cirrhosis of the liver, in Columbus, Arkansas, December 11th, A. D. Pope, M.D., in the 67th year of his age. Graduate of Transylvania College in 1835.

SANDFORD.—On Sunday morning, December 12, 1880, of diphtheria, Dr. Wilbur F. Sandford, of Greenpoint, Long Island, in the 36th year of his age.

OL. MORRHUÆ. OPT.

PHILADELPHIA, September 10th, 1880.

A personal visit to Norway has enabled us to gain information of great value regarding **Cod-Liver Oil,** and to secure supplies of a quality incomparably superior to any that has yet been obtainable in America.

We have the pleasure to announce that we have engaged the entire product of

Borthen's Fishery, in the Halten Islands, which Oil obtained the highest prizes in Paris, 1878, and the present year in the Great Exhibition of Fishery Products at Berlin, and which has also received the endorsement of many of the most distinguished members of the medical profession in this country.

Physicians desiring to prescribe this useful remedy can secure it in its very finest condition by ordering

BAKER'S COD-LIVER OIL.

Baker's Emulsion, C.L.O. and Hypophosphites of Lime and Soda, made with the above Oil, will be found of similar excellence.

Pamphlets mailed on request.

Agents for Barlett's Pile Suppositories.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O	
Quinidia do	15 "	20	24	2	2	
Cinchonidia do	15 "	C	H	N	O	
Cinchonia do	15 "	20	24	2		
Chinoidine Purified,	30 "					

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

ENDOCARDITIS.

BY ALONZO CLARK, M.D., LL.D.,

President and Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons, New York.

(*Concluded from page 7.*)

Relating to endocarditis, the matter of vegetation, commonly so called in this country, is of interest. I told you that endocarditis is sometimes attended by little granulations growing out of the endocardium, firm at the base and soft at the top, not so large as a pin's head; and that these, though of very dimunitive size, are capable of being the nodus around which the fibrine of the blood will coagulate—that is not a good word—will be gathered, and become of visible form, and that we usually call vegetations. The German writers regard it as an accretion, and we are all correct in regard to its nature, that it is substantially the fibrine separated from the blood in the same way as it is separated when a thread is run through an artery or vein. Any cause that produces roughness, as an ulcer or any irregularity, is liable to be surrounded by this accretion of fibrine. Here you observe is an ulceration of the valve, and it has acted as granules in endocarditis may. Here, again, you have an accretion, probably from mere roughness, without the granules; mere roughness from inflammatory exudation. I told you, the other day, that while we rather rarely see a membranous exudation in endocarditis upon the body of the heart, on its inner surface that can be easily accounted for, under the supposition that the exudation has thickened and fallen off by the continual washing of that surface by the current of blood that passes through. In this specimen you see some deposit of fibrine on the three aortic curtains. And here is that rather interesting—I don't know but I ought to say ornamental—formation of granules, forming a semicircle on the free portions of the valves. This, however, illustrates atheroma, which subject I wish to reach before the end of the hour, and I will retain it for the present.

One of the dangers, I told you, of endocarditis is the occurrence of these deposits and the washing of them away into the general circulation, and, finally, the lodgment of a mass of this kind in an artery, through which it cannot pass on account of its smallness. Endocarditis of itself is almost never fatal. It accompanies pericarditis in a great majority of the cases of pericarditis, and for the most part, when so associated, depends upon the same cause. Yet endocarditis can occur even in the acute form, and frequently it does occur in the chronic form, without any rheumatism preceding it, without any of the diseases that are apt to be associated with pericarditis, as Bright's disease, scarlet fever, the purulent inflammation of the body, septicæmia. I have sometimes, by exclusion, been able to say that a certain person has endocarditis. The only mode of arriving at such an opinion is by finding a certain amount of febrile action, a little elevation of temperature, a little increased frequency of the breathing, and a short, irritable, quickened beat of the heart. That short, irritable beat will produce in the ear the same sound that I referred to in describing pericarditis; when it was first noticed it was regarded as diagnostic, but it has no such value. It is just that metallic ring which

you get by applying the palm of the hand to the ear to exclude the air and then striking on the back of it. It is the irritable beat of the heart against the inner wall of the chest that produces it. And then, you should be able to exclude everything that would be likely to produce a febrile movement, and perhaps you may, in half the cases, find that the diagnosis of endocarditis is verified by after indications. During the progress of endocarditis there are frequently no indications of its presence except pericarditis. You assume, usually, at once, when you diagnose acute pericarditis, that there is endocarditis, but of itself it does not give distinctive signs except in a few cases. When, for example, you have, say rheumatism or Bright's disease, and have listened to the heart on a certain day and found nothing unnatural, you find the illness is increased a little, the heart beating more frequently, the respiration short and frequent, you listen again and you get an endocardial murmur. It is probably soft. It may be at the aortic opening; it may be at the mitral. Supposing it to be in the interval of the heart's action, during the period of repose, it is produced by one of two things: An œdematous valve, or these little granulations I have been describing to you forming upon it, on the surface that the blood has to pass over. In a few instances you may have that aid to diagnosis, but in the majority you do not. Then, again, there may be an œdematous swelling of the aortic valve; the two folds that constitute the valve are swelled out and partly fill the passage through which the blood should flow. A soft murmur is sometimes produced in that case, but as it is only sometimes it cannot be relied on as a diagnostic mark, except when you have listened a few days before and found no murmur, and now, with indications that there may be endocarditis, you do find one, then it is significant; but, in practice, neither the rational nor the physical signs of endocarditis are sufficiently marked to enable anybody to make a certain diagnosis without one of these facts that I have just now referred to. In general, endocarditis comes during its acute period without producing any symptom, only that short irritable beat of the heart and the increase in the frequency of the respiration. The rational diagnosis is entirely vague. Then the physical diagnosis is very uncertain. But the after diagnosis—you may lock the door after the horse is stolen—the after diagnosis is sure, or next to sure. The deposit in these valves, if it is anything more than œdema, is pretty sure to produce changes in the structure of the valve. In the first place, they must be thickened, for there is new matter deposited in their structure; in the second place, this new matter undergoes a sort of organization. It behaves like a false membrane, and shortens, and the valve is shortened, so that when it attempts to fill the opening that it is appointed to fill it cannot. There is a hole left in the middle. Then, as I told you, the valve sometimes grows hard and stiff, like leather, and can do very little in preventing the return of blood, and a good deal in preventing the outflow of blood, being obstructive. Well, when these changes occur, even in a moderate degree, you will get a murmur. It will very likely be of a harsh kind. It is not certain to be that at first. It will grow to be a harsh murmur, in all probability, in a few months. The period of time, however, when you can recognize these murmurs will be from three weeks to three months after the disease has passed, after the time when your diagnosis would be of any practical value. But the thing stands so. You have to take it as it is. You can pretty safely say, after two or three months, this patient has had endocarditis. But as it is so frequently associated with pericarditis, and pericarditis is pretty easy of recognition, and as, further, the treatment of the one condition is the same as the treatment of the other when they are associated, this lack of power of diagnosis is not so disastrous. It is only important when the disease occurs alone; and that it does occur alone we have pretty good evidence in the great number of persons that we see with valvular disease who have never had rheumatism, never had Bright's disease, never had any of the affections that are so apt to precede pericarditis and endocarditis. They have enjoyed, as they believe, good health, and cannot point back to any time when they have had symptoms that would lead us to think they had heart disease; yet the valves have become thickened, and are defective, just as they are in the acute form of the disease. There is then, undoubtedly, a chronic endocarditis, that only shows itself by the physical changes that are produced, or rather by the changes that are produced in the sounds of the heart. The relation of these changes to the structure of the heart itself will be for consideration hereafter. You observe, then, you have not a very certain diagnosis. Only when you have listened and heard no endocardial murmur, and then, a few days after, with symptoms of illness, do find one; that is about your only guide. And then you have to be certain that it is endocardial and not exocardial. The statement I made the other day, with reference to the breathing, will aid you in making the diagnosis.

With regard to the treatment, if it occur in connection with rheumatism, as it often does, the treatment for rheumatism is the best treatment for endocarditis, as it is for pericarditis. If you can recognize the disease as occurring alone, then I would advise the abstraction of a little blood; unload the vessels; relieve the valves of a part of their work – not, however, more than eight or ten ounces. You will be tempted to apply counter irritation over the pericardial region. Well, that is orthodox, but it is useless. There is no way of affecting, by counter irritation, the circulation in the endocardium. It is entirely dependent upon the coronary arteries of the heart, and these are given off at a point that you cannot reach to influence the amount of blood circulating in them by any outside application. But if it will satisfy you better, if your conscience tells you the patient ought to have a blister, put on one—it will prevent your listening so satisfactorily; at the same time settle it with your conscience. It will do no harm, and I don't believe it will do any good. In quieting the heart's irritation a moderate dose of opium is of value. The more quietly the heart can do its work, the fewer the embarrassments, the less the mischief that will follow. The strain upon the valves, whenever they are brought into exercise, is considerable—that against the mitral when the heart is contracted; that against the aortic valves after the heart is contracted, while the artery is contracted. So that if the heart does its work in the quietest possible way the mischief to these valves will be the least that you can expect. Then you have really only two things that are of much consequence, and those two are the abstraction of blood and quieting the heart with opium or some other anæsthetic.

There is another form of endocarditis which has been lately described, or within a few years at any rate, that you will not be able to recognize at all. Still, it is well enough that you should know, and important that you should know such a disease does exist. It has been called ulcerative endocarditis. It seems to be a sort of diphtheritic inflammation. A diphtheritic inflammation of a mucous membrane, of the trachea, for example, or of the fauces, differs from a common croup or other membranous inflammatory action in the fact that the deposition that is the result of the inflammatory action is to a certain extent incorporated with the membrane; so to speak, infiltrated into it. A croupous membrane can form and can exfoliate and leave the membrane entirely. A diphtheritic membrane can exfoliate, but it is not likely to leave the membrane perfectly sound and normal. Sometimes it does, but it is the tendency of diphtheritic inflammation to deposit the products of inflammatory action in the tissue. Well, that seems to occur in the endocardium, and it may occur in any part of the endocardium, not alone in the valve. It does not occur so frequently in the valves as on the body of the endocardium. I should be disposed to regard it as a sort of diphtheritic inflammation. The new deposit looks like a membranous patch. It is in patches. It does not extend over the whole surface; and when you examine it post-mortem you will think you can wipe it off with your scalpel, or with a rag, but when you attempt to do it it holds fast, and if you with your scalpel attempt to remove it you remove the membrane with it. This proves to be ulcerative in its results. It is not ulcerative in the beginning. It is simply a deposit of diphtheritic membrane on and in the endocardium. But it has not the power to perpetuate its life, if it has any, and in a little while it will begin to break down—to break down into fine granular matter, and perhaps some oily products and as it does this it destroys the membrane in which it is deposited. The endocardium, then, is susceptible of destruction in limited portions of its extent, in this way. As the inflammatory exudation breaks up and disappears, it carries with it a portion of the endocardium. If that occurs upon the valves, as it sometimes does, it is very likely to weaken that half of the valve, that layer or fold of the valve, so much that aneurism may take place in this valve. That is, the remaining membrane, the membrane that forms the other half of the valve, will not bear the strain that is brought upon it by the regular course of the circulation, and it pouches; it makes a bag, or, in other words, an aneurism, and it has been known to rupture under these circumstances. Then, again, the ulcerative process may not be confined to the endocardium if it occurs upon the body of the heart. It may penetrate a little distance into the muscular layers and weaken them, and hence also aneurism of the heart has occurred, or rupture of the heart. This, as I have told you, is a form of inflammation, or a product of inflammation that you cannot recognize during life. It produces no physical signs. It produces no peculiar rational signs. It may be found hereafter that it is confined to those who have some diphtheria in other parts of the body. And at this point I may as well say to you that when diphtheria made its appearance in New York for the first time as an affection of the throat and air passages, I was interested to

know what sort of thing it was, and I early procured specimens of the membrane for microscopical examination. I found that it was made up of granules in great degree; granules that were held together by a pretty firm matrix, and that the matrix was transparent; that on the outside of the membrane, that is on the side exposed to the air, there were the common microscopic vegetations, two or three forms of them. And that in this respect the diphtheritic membranes differed from the true croupous membranes, being constituted, in very considerable part. of granules, and in part. also, of ex traneous vegetations. At a later day it was claimed that these granules were a particular vegetation of themselves. and they have received a name, micrococci—I do not know that it was a *cock-eye* that saw them!—Micrococcus means a little berry. These bodies are rounded, and in these membranes are packed together pretty closely. As you read the journals and new books you see a good deal of micrococcus. It seems to have found its way into parts of the body that have been supposed before to be sealed to any outside thing. Well, they tell us that ul cerative endocarditis is a consequence of the deposit of micrococci. They are little bodies, not more than the one twenty-five thousandth of an inch in diameter. They are very minute, therefore, and it is claimed that this deposition in the endocardium is made up in very considerable degree of these little microscopic bodies. That would only bring it into closer affinity with diphtheria if it prove to be true. And even if it is true I do not believe that the micrococci are micrococci at all. I think it is a particular form of deposit of lymph in granular shape, and certainly there is no proof that they are vegetations. It is a mere statement of opinion by somebody, and that opinion has. like a wave, spread pretty far. I am willing to admit that the subject is under judgment. is under arbitration, and it may prove that these bod'es are little vegetations. and that they are proliferated by scission, as it is called; that is, divided, and each one taking the shape of the parent—a pretty rapid way of multiplying. If you have one in the beginning, and it divides and makes of itself two, and the two divide and make of themselves four, and the four divide and make of themselves eight, and this division goes on pretty rapidly, you will soon get high numbers. You understand me! I do not deny the possibility of this being a vegetation, but the probability of its being a vegetation is very doubtful in my mind. Still, that sort of thing does occur in the endocardium; a something that has a granular form is deposited, and afterward leads to ulceration.

It is necessary to refer to other causes of valvular diseases. The most common is the deposit of that substance that looks like mucine, that I have described to you. Then its organization and contraction, producing what I have already denominated the shortening, thickening and stiffening of the valve. Those same results can be obtained when other agents are at work. One of the things that operates most actively after inflammation is atheroma. Atheroma originally meant an abscess, but it has come to mean, in these later years, a particular deposit that is confined almost entirely to the heart and arteries, much more common in the arteries than in the heart itself, but in the valves not infrequently met with. This atheroma you can form an idea of by the specimens which I can exhibit to you. Here, for example, is the beginning of the aorta, and you observe it is pretty large, and it looks, to a certain extent, warty. It looks as if it had been flattened, and on one particular point there is a little deposit. and a transformation of a deposit into calcareous matter. Well, that is atheroma. When you first find it in the dead body it is almost always of a yellow color, or a faint yellow color. Here it is white. It has been bleached by alcohol, in which the specimen has been kept. If you handle the specimen you will find that at different parts it is of uneven thickness. There are little warty, flattened eminences upon the whole circumference of it. and here at the edge you can get an idea of its thickness. Here is another artery that is, to a certain extent, warty, exhibiting the same thing, lacking the yellow color which belongs to it when it is first seen. You observe it runs up the artery a considerable distance, that is the aorta. You observe, too, that it has narrowed the openings of the three arteries that are given off from the aorta. Here is an interesting specimen of an atheromatous deposit in a valve and not in the artery, or if any, very little. The valve has undergone one of the changes that I will describe to you directly. and it has ulcerated a hole through the valve. Not only that, but it seems to have been deposited on the substance of the heart, probably not in the substance, and an opening has been made at the same time from one ventricle to the other. A broom straw has been passed through the whole, from one ventricle to the other, and you will observe what an ulcerated and damaged condition this valve is in. Here are a number of other specimens which you will examine.

Now, then, the first question that comes is, what

is this? This atheromatous matter? Well, it is an effusion on the outside of the inner lining of the artery; the intima, as it is the fashion to call it now. It lies outside of the lining membrane of the artery, that is measuring from the centre of the artery and calling it out in every direction. It is to a certain extent infiltrated into the fibrous tissue of the artery, but it is much more commonly found just between the lining membrane of the artery and the fibrinous layer, called media in these later days. Between the intima and the media, then, is to be found this deposit. And it is constituted sometimes of a material very much resembling that that I have described to you as thickening the valves in endocarditis, a sort of mucous matter, and that is thick set with cells that do not grow, do not develop themselves according to the rules of cell growth in other parts of the body, but become attached to each other on almost any point where they may touch, and thus form a kind of tissue. Then that is pretty fully infiltrated with little globules of oil, and occasionally a few fibres are formed by the coalescence of these cells, but they possess very little power of permanent life. And the result of this is a pretty early change in their constitution. The cells disintegrate and oily globules seem to take their place. The fibres gradually disappear, being broken down into granules, and soon the means of organization have passed. It is very soon, that is in a few months, or a year or two at most. The result of the breaking down of the structure is a softening, and you can sometimes find these little deposits of soft material, looking exactly like pus, except a little yellow. Put it under your microscope and you will find that there is no pus globule in it, not one. The result of this is, sometimes, to leave an ulcer on the artery, or, as in the specimen you are examining, in the valves, and more frequently at the base of the valves than at any other part of them. A weakening of the structure is therefore produced, without softening. This atheromatous matter has no strength, and it has no elasticity. It cannot replace in function, as it replaces in position, the fibrous tissue of the artery. The wall grows weak by the deposit of this matter in it, therefore. and you may start, with regard to aneurism, with this assertion, that aneurisms in the human body do not occur except by violence or by the weakening of the coats of the artery through an atheromatous deposit.

An aneurism in any of the large trunks of the circulatory system will not occur without atheroma; it must be weakened before it will yield, and weakening is always effected by an atheroma of the artery. You may search for twenty years among aneurisms, and you will not find a single one that has occurred in a sound artery. Even those minute ones that have been lately described in the brain circulation, have for their base atheromatous weakening of the arteries of the brain. Well, this is a pretty grave matter, then, for it is the parent of aneurism; it also produces the weakening that precedes what is called dissecting aneurism. The artery may break partly in two, the inner layers may be broken, and the blood may find its way between the layers of the artery for a very considerable distance. This, however, I believe only occurs in the large arteries, the thoracic and the abdominal. I do not know but it occurs in the iliac sometimes. That also, I say, has its origin in the weakening of the arterial coats by this atheromatous deposit. Well, this is one of the courses that an atheroma pursues when it is once deposited in the vessels. Another is interesting perhaps, not to say important, in its bearing. The atheromatous matter is broken down very much in the same way as I have described to you, but more gradually, and the fat seems to be taken up by the circulatory vessels, and deposited in the place of the atheromatous matter is bony structure, bony scales. Such a specimen as that I will try to show you the next time we come together, in which the whole artery has been converted into scales, a multiplication of scales, some of which have a real bony structure—have the lacunæ and the canaliculi; and some of which are mere calcareous accretions, without anything which distinguishes bone. These render the artery inelastic, and so interfere with the circulation. As I have already told you, the heart sends the blood into the artery and dilates it, and the artery, by its natural contractile power, propagates or continues the action produced by the heart, carrying the blood forward in the circulation. But in an artery that has been deformed in this way the elasticity is gone. Hence, in such cases it is not uncommon that hypertrophy occurs. There is another evil that may come of these bony scales; they are sharp at the edge; they are thin. I say sharp; they have almost a cutting edge; and the gradual action of the artery, or so much as is left of its capability, may cut through the inner lining and let one of the sharp edges stand out like the edge of a nail, or the end of a nail rather, and on this may form the accretions of fibrine, the coagulations of fibrine, or vegetations, and these, in their turn may wash off and make emboli. In a few instances, when the process is softening, and it has occurred between the valves, the soft mat-

ter may remain between the valves some time. I had a specimen, I do not know but I have it now, but I have not seen it for two or three years, in which the mitral valve was the seat of atheromatous deposit, which softened and made a material looking like pus, and remained for some time; I do not know how long. It was found after death. It at first merely separated the two folds of the mitral valve, and formed a kind of abscess. The quantity of softened material it contained was perhaps half a teaspoonful; it had not, as in the specimen you are examining, destroyed the lining membrane, or at least the folds of the valve.

There is one other point to be referred to in this connection. You hear a good deal, or something, at any rate, of bony deposits in the heart, and particularly in the valves. They almost always result from a changed atheroma. The atheromatous matter is deposited in the valves, and there is, perhaps, some thickening, too, from inflammation, produced by the irritation of this substance, and at length absorption of the material takes place and calcareous matter is deposited instead. I shall be able to show you, probably, two or three hearts, perhaps some in which you can feel the bony roughness in the valves. Occasionally this bony deposit occurs in the heart itself.

I was consulted in regard to a physician who was pretty well advanced in life. It was supposed that he had heart disease. His heart was beating irregularly, sometimes palpitating, sometimes beating very feebly, and he was subject to fainting spells. On examining his heart I found no enlargement of it; I found nothing to indicate valvular disease, and I said, from the manner in which it behaved, there must be some disease of it, but I cannot tell what. In a month or two this gentleman died, and a post-mortem examination was made, and a mass of calcareous matter was found in the body of the heart, beginning at the base and extending downward an inch or more, and, to a certain extent, thickening the particular part of the base of the heart in which it was deposited. It had crippled the heart in its muscular contractions and the heart resented it as well as it could, but it could not tell the story to the outsider. It was plain that the heart was not working properly, but why, nobody could guess, because there are other forms of diseases that behave in the same way, particularly the fatty degeneration, Quain's degeneration of the heart. You can frequently see that there is something wrong with the heart, but you cannot tell what it is. This atheromatous matter is not usually deposited in the muscular fibres of the heart, and whether it was the result of a previous deposit of this material in the heart, or whether it was a bony deposit or a calcareous deposit that was in connection with atheroma, I cannot tell. The importance of atheroma, then, will impress itself upon your minds mainly with reference to the deposit in the valves of the heart and the formation of calcareous or bony concretions in the valves, or, perhaps, in the substance of the organ. There is no way of distinguishing, before death, these several forms of diseased valves. You cannot tell, as you hear a certain murmur, whether it is produced by inflammation of the pericardium or by an atheromatous deposit or atheromatous deposits that have passed into calcareous or osseous formation. To determine this you will have to wait until after death, and as almost all, and probably all, these vegetations of the valves are remediless, are not curable, it is of no very practical importance.

A remark or two more in regard to endocarditis, before we go to diseases of the valves, to consider them in detail. Endocarditis, like pericarditis, is very apt to act, to a certain degree, upon the heart itself. An œdematous effusion may take place in the fibres of the heart, exactly as you see an œdematous effusion occurring in the leg when the knee is the seat of inflammation, or in the arm when the muscles of the shoulder are involved in inflammatory disease, as rheumatism. For example, in February of last year I woke one morning with a pain and stiffness in the left shoulder. I found that I could not get my coat on without assistance. The shirt was big enough to go almost anywhere, but the coat was made to fit a little more closely, and I could not get into it, so I got assistance to put on my coat and then went about my business. But the arm grew worse and worse, and I recognized, after a few hours, that I had rheumatism in the deltoid muscle, and directly my arm and hand began to swell and my hand looked very fat. As soon as I saw it swelling I took off my rings, for fear they would be fastened upon the finger and could not be gotten off. The swelling continued until, after a pretty free use of the bicarbonate of soda, the inflammation was subdued. Then the swelling all went away. So in the heart, the parts neighboring to those that are the seat of inflammation may become the seat of œdematous effusion, and thus weaken the heart—the same thing that I stated to you when speaking of endocarditis. Pericarditis and endocarditis commonly occur together, and, of course, there will be all the more of this œdema of the heart.

Communications.

FIXED DRESSINGS AND THE METHODS OF APPLYING THEM.

BY GEO. F. SOUWERS, M.D.,
Of Philadelphia.

While fixed dressings have, for the past few years, occupied the attention of the profession to a greater or less extent, there yet seem to be a number of physicians who are not thoroughly conversant with the manner of application of the different forms of this most useful adjunct to surgery, and it is to this class, represented largely by those practicing at a distance from the great medical centres, that I believe a paper of this nature would be of value.

While under the old regime of fracture dressings, of the lower extremities more especially, patients were compelled to maintain a recumbent position for four, six, eight or ten weeks, often exercising upon the system, especially in old persons, a very deleterious influence, under the new dispensation they may frequently be allowed to go about on crutches at the end of nine or ten days, or, at furthest, two weeks; the limb being encased in a light, clean, supporting case or splint, that can readily be removed and replaced at pleasure. In this box, for such it practically is, formed by a fixed dressing, the limb rests securely, and beyond any displacing power of the patient short of cutting or crushing, and, at the same time, an equable pressure is maintained. These dressings have been brought into prominence, not so much by their use in fractures as by their applicability in the various forms of Pott's disease of the spine. Though there are many different kinds of material employed in the making of these dressings, the principle involved is the same in all, to wit: a dressing that shall be easy of application, that shall harden rapidly and yet not easily chip or loosen, and that shall afford a firm, equable support to the injured limb.

The first thing to be considered in the making of these dressings is the bandage, and the degree of tension exerted in its application; for ordinary use the simple roller bandage, about two and a half to three inches in width, is employed; if a muslin or linen bandage cannot be obtained, there are a vast number of materials that serve the purpose equally well; strips from an old felt hat may even be employed in an emergency, toweling of the ordinary common crash, or newspapers even, may be employed, the idea involved being to use anything that will absorb and maintain within its meshes or pores the solution employed for the application of the plaster-of-Paris dressing; however, it is better to use a coarse crinoline or mosquito netting, experience having shown this to make the best and most convenient bandage; the employment of these materials is not, however, an absolute necessity.

In the application of all fixed dressings care must be taken that they be not applied too tightly to the limb; there must be an allowance made for shrinkage in the moist bandages, this shrinkage being considerably more than would at first seem possible; in fact, in some forms of dressing, as in the silicate, for instance, the roller should be applied quite loosely, even bagging a very little. As to the time of application of these dressings, so long as any swelling is present, the fragments of the bone not in correct apposition, or, at least, in as correct apposition as they are likely to be, or if there is a spasmodic, irritable condition of the muscles, there should be no resort to their employment; in from a week to ten days, however, as a general rule, their application may be safely proceeded with, this being the rule commonly followed at the Pennsylvania Hospital, in the service of Dr. R. J. Levis, to whom I am indebted for a number of suggestions in the preparation of this paper. Further, care should be taken to see that nature is making an effort at reunion of the fragments, before applying a fixed dressing. As to which are the best and most reliable dressings every surgeon has his own opinion, though as between some there can be but very little choice; true, the matter of expense enters largely into the consideration of which bandage shall be employed, but as in a great many other things, it frequently occurs that the more expensive article is in the end cheaper than that of low cost. At different seasons of the year, too, different bandages present different degrees of availability; thus, that which in the winter time makes a very elegant and cleanly dressing, may be a very unpleasant if not an uncleanly thing to use in summer; thus, while adhesive strips make a nice winter dressing they are somewhat objectionable as a summer application.

In selecting a muslin to be employed in the manufacture of a dressing it is not desirable to secure one of a very fine and close texture, a rather open mesh being generally more desirable; thus crinoline, mull, crash toweling, and goods of a similar texture make perhaps the most satisfactory bandages; further, an unbleached is preferable to a bleached muslin; it does not appear to be as stiff, and consequently can be

more readily wrapped or moulded into position. An unglazed paper, or bookbinder's muslin, if obtainable, forms a very nice material for these dressings. It is not a bad plan to follow, to wash or soak, and then dry the material, before using it as a bandage, the reasons for which are evident without being discussed.

The simplest forms of fixed dressings may be made from articles which are always to be found in the kitchen: thus, for an emergency application, that is to last but for a short time, a paste of flour and water may be employed, as follows: A roller or crinoline bandage having been passed around the limb, the mixture of flour and water is rubbed into the meshes of the cloth; over this, while still wet, another layer of bandage is placed, and into this also the mixture is rubbed; one layer after another is thus superimposed, until the necessary strength and thickness (the amount of which each must judge for himself, according to the case in hand, though four layers are generally sufficient) are obtained, a plain unbleached roller bandage is placed over all, and the dressing is complete. A nicer and more reliable way of making this bandage, and one which dries most rapidly, is to add to the flour and water the white of one or more eggs, and enough gum arabic to give the mass a sticky sensation when pressed between the fingers; prepared in this manner the bandage presents a more elegant, cleanly, and shining appearance. Instead of the gum arabic, glue may be employed, or, in fact, a dressing of glue applied to an ordinary bandage will make a very simple and at the same time very efficient and strong dressing.

Next, perhaps, in order of simplicity, is what may be styled the newspaper dressing; this consists simply in the use of newspapers, where bandages cannot readily be obtained; whichever application or dressing is to be employed is rubbed into the paper in the same manner as into the roller bandages. When possible, tissue or some similar paper makes a lighter, less bulky, and more readily applied substitute for newspapers.

There is a form of dressing which, while simple, is very efficient, and I am tempted to add unusually economical, in that it uses up what would otherwise go to waste. I refer to the felt dressing; an old felt hat cut into strips about two inches to three inches in breadth, and these allowed to soak for some minutes in *boiling* hot water, can be thus made to do duty after having served its day as a head covering. These strips, when thoroughly saturated, should be squeezed as dry as possible, and then moulded to the limb or part to be splinted; having been moulded into position a roller is passed over it, and the injured parts rest in a light, strong, and not readily displaced box. Binder's board thus treated makes also a most desirable dressing; both of these materials are particularly adapted to injuries about the lower jaw, as they accommodate themselves admirably to the angles and curves of the bone; of course the same remarks will apply to any species of felt cloth or paper.

The pasteboard dressing may be modified and strengthened by rubbing boiled starch into it, the consistence of the starch being about that used by wash-women. A nicer and more reliable way (suggested by a friend) of applying the starch and pasteboard dressing is as follows:— The limb is surrounded by a layer of cotton batting, the protuberances, etc., being protected by rings of cotton; ordinary binder's board, $\frac{1}{16}$ to $\frac{1}{8}$ of an inch in thickness, cut as nearly as possible to fit the limb, and soaked first in boiling hot water, and then in starch, is then applied; over all, a bandage soaked in thick starch is placed, and over this a plain roller; under the use of hot sand bags this bandage dries in about twenty-four hours. Seutin, of Brussels, I believe, first called attention to the starch bandage, about 1834, and he sets it down as a rule, that about thirty to forty hours are consumed in drying, so that the two extremes may be said to be twenty-four and forty hours. This bandage may be readily cut open to examine the injured parts; if placed on while any swelling is present it should be removed when sufficient time has elapsed for a full subsidence of swelling, and a strip cut off of the front of the dressing; it is a better rule, however, never, if possible, to have occasion to cut a fixed dressing on account of subsidence of swelling; this process should have taken place before the application of a permanent dressing, as otherwise very serious trouble might arise, due to the exertion of an undue amount of pressure, etc.

Paraffine, or even tallow candles, may, in an emergency, serve a good purpose; being melted they are poured over the limb, which is surrounded by a roller, the grease being rubbed into the meshes; as it hardens it makes a strong case in which the limb rests easily. Melted wax may also be employed in this manner. In our Southern States, especially in cool weather, and in sections where more elegant preparations are not easily obtainable, ordinary tar is employed in the manufacture of fixed dressings; though, of course, this can hardly be said to make a very nice form of dressing, still, it is an exemplification of the fact that necessity is the mother of

invention. Almost any gummy or starchy substance may be made to do duty in these dressings; thus tragacanth, in the form of a thick paste, is very frequently employed, this being, like starch, gum arabic, etc., simply rubbed into the meshes of the bandage. Ordinary shellac may be frequently and advantageously employed; this is boiled and the bandages dipped into the solution, and then applied; it makes a very clean and nice dressing; in fact, I see no reason why an ordinary strong shellac varnish, applied in the same manner as the silicate dressing, should not be employed, the alcohol being rapidly volatilized. Splints of gutta-percha may be formed by plunging this substance into boiling hot water, in which it very rapidly softens, and then moulding it to conform to the limb, a bandage being also passed around it.

In cold weather superimposed layers of adhesive strips make a very nice, and at the same time inexpensive and an easily removable dressing. The strips should overlap each other for one-half their width. This form of dressing is peculiarly applicable in fractures of the ribs, where it serves to limit the amount of chest expansion. In summer, however, the strips do not maintain their positions well, and they are not so cleanly as many other forms of dressings. In the application of this dressing care should always be taken that the parts are well shaved before the application of the strips, as if this precaution is neglected there is apt to be considerable trouble and pain to the patient, experienced in their removal.

I come now to consider the more expensive and the more difficult form of application of these dressings. In the order of merit and ease of application, silicate of sodium, or soluble glass, as it is sometimes termed, takes precedence; this preparation is obtainable at all drug stores, and makes a very available form of dressing, as it can, in a manner which I shall describe, be readily removed from the patient, for the purposes of examination. The best method of applying this dressing is to envelop the part in a crinoline bandage about two and a half to three inches in width, the solution of the sodium silicate being applied between every layer of the bandage by means either of a brush or the hands; over all a coating of the solution is painted or rubbed; this form of dressing takes about four hours to harden, and it may at any time be removed by slitting it up in front by means of a pair of shears or heavy scissors. If desirable to replace the bandage it is simply sprung back over the limb and bandaged into position. In the application of this, and, in fact, all permanent dressings, care must be taken that too much pressure is not exerted on salient points, this being avoided by guarding them by means of a layer of cotton, or a piece of soft lint folded.

There is another form of permanent dressing, known as the "zinc and glue dressing;" this makes a very strong, white and rapidly hardening dressing. It is made in the proportion of one part of zinc oxide to either four or six parts of glue, say one-sixth of a pound of oxide of zinc to one pound of glue, with sufficient water to make a thick solution; care must be taken not to have the dressing brittle, but by using these proportions there is not much danger of this accident. This solution is applied, while still warm, by means of a brush, and may, if desired, be finished off with a roller, but this is hardly advisable or necessary, as the elegance of the dressing does not make it in any way objectionable to the sight. When a brush is not conveniently to be had, the hands may be employed to rub in this dressing; and at this point a little hint that may be of value occurs to me; it is always advisable, in applying these fixed dressings, where the hands are employed in rubbing, to oil the hands, as they can thus be more readily and thoroughly cleansed, the material not adhering so closely to them.

The next form of dressing to be considered is that which is perhaps more known and more often applied than any other. I refer to the one which Dr. Sayre, of New York, has made so much use of in treating Pott's Disease of the Spine—the plaster-of-Paris. While this form of bandage presents many advantages, yet there are some objections to it; it is more or less liable to chip and leave in the track of the patient a series of plaster fragments, this being more especially the case when the dressing has been put on with a lavish hand; further, if a number of bandages are prepared at once they are apt to be useless when wanted, unless they have been kept in a dry place. The method of making and applying this bandage is as follows: Into the meshes of a coarse crinoline, or crash, dry plaster is rubbed; or another method, which consists in the employment of an apparatus specially constructed with a view to the preparation of these plaster rollers (if they may be so called), may be used. This apparatus consists of a box filled with dry plaster, through which the crinoline, in strips of from two to four inches in width, and six yards in length, is drawn and wound on a small iron bar, which is turned by means of a crank-handle; the bandages prepared by rubbing the plaster into

the meshes of the cloth are, however, fully equal to those made on the machine. The crinoline thus prepared should be made into an ordinary roller, and if not intended for immediate use should be enclosed in a tin, or other air and water-tight box, and placed in a cool, dry place. A little salt added to the plaster makes it set more rapidly. When needed for use all that it is necessary to do is to dip the roller into cold water, for about three or four minutes, or until air bubbles cease to rise, the plaster thus absorbing enough water to make it set nicely. The part to which the bandage is to be applied should be cleansed by means of tepid water, and lightly but thoroughly dried; this precaution should, in fact, be exercised before the application of any permanent dressing, no matter of what kind. Before commencing the application of the bandage the limb should be surrounded by a layer of lint stitched into place, and having attached to it (in the case of dressings of the lower limbs) tapes along the upper aspect. These tapes may also be employed in many of the other dressings, and be a very convenient arrangement for the purpose of suspending the limb when necessary, and allowing it to swing. If lint be not readily obtainable, a piece of blanket will answer equally as well; some prefer passing the suspending bands around the limb; if this is done, leather bands about half an inch wide are far preferable to muslin or linen, as the leather does not work into strings that exercise more or less of a cutting influence.* The crinoline roller is then applied in the manner of any ordinary bandage, plaster of the consistence of a thick paste being rubbed between each layer of the bandage. A sufficient amount of roller having been wound around the limb, the dressing is finished by rubbing wet plaster over all till a perfectly symmetrical appearance is presented; if necessary, a little dry plaster may be dusted over the final coat of the dressing; this dressing hardens very rapidly, say in about thirty minutes. Three or four bandages of the lengths given above are generally sufficient to afford the requisite support. If it is desirable to remove the dressing at any time, it can readily be done by slitting it up in front by means of a shears, and the same bandage can again be placed on the limb and confined in position by a roller. In from two to four hours the bandage is ready to be thus cut open when desired. If too hard or thick to cut, by soaking the plaster in *hot water* for fifteen minutes the object may be easily accomplished. It may at times be desirable to employ what might be styled a partial splint of this material, and this may be done as follows (this form being used when it is desirable to observe frequently an ulcerated or lacerated part): A piece of blanket long enough to reach above and below the parts to be examined, and fifteen inches in width, should be dipped into a plaster solution of about the consistence of cream; this is then folded so as to be two to three inches in width and applied along the part not to be observed, being confined in position by circular turns of the bandage above and below.* Where subject to discharges from wounds and to water, etc., oiled silk forms a very nice protection to the bandage. This dressing has gained a high reputation, from its extended and successful employment in the various diseases of the vertebræ, from the fact that it supplies the necessary amount of support which the vertebræ in Pott's Disease are unable to afford.

In applying the plaster dressing to the trunk, a number of modifications are necessary, or can be made: thus, the crests of the iliac should be provided for by fenestræ in the bandage, these being cut with a knife after the dressing has hardened, say in about three hours; in like manner, any other prominences may be provided for; fenestræ, if necessary, may also be made for the mammæ in the female. Many surgeons, for the sake of ventilation, and to decrease the weight of the apparatus, perforate this plaster box, as it is, at different points, the openings varying from the size of a cent to that of a nickel, or two-cent piece; where an unusual amount of support or force is necessary, strips of whalebone or flat steel springs may be introduced between the different layers of the bandage as it is applied to the body. When employed for the treatment of spinal affections, it is necessary to suspend the patient before commencing the application of the bandage; to attain this object, an apparatus consisting of a tripod, from which hang chin and armpit supports, is generally employed. A board placed between two projecting bookcases, or a hook driven into the ceiling, afford, however, equally good points from which the patient may be suspended. A thin gauze, skin-fitting undershirt should be placed on the patient before applying the bandage. This dressing has, of late, been somewhat modified by a gentleman of Chicago, whose name has escaped me. It is a well-known fact that sole leather, when thoroughly soaked, can be moulded into almost any shape, and that when drying it retains the shape of any object over which it

* Hamilton on Fractures, etc.

* Hamilton.

has been stretched; on account of this property it of itself makes a very good permanent dressing. As suggested by this gentleman, the leather is best adapted to the accomplishment of the desired object in the following manner: The plaster-of-Paris dressing is applied as already described; just before becoming thoroughly hardened the plaster jacket is cut open in front and removed from the patient; an accurate mould of the body is thus obtained; into this mould plaster is poured and allowed to set, over this final cast wet sole leather is stretched and permitted to dry. A leather jacket that accurately fits the angles and curves of the body is thus obtained; for ease of removal this jacket is slit open in front and eyeleted, thus permitting of lacing, fenestræ being cut as in the ordinary plaster dressing. This jacket, if necessary, may be strengthened by flat steel springs running perpendicularly; from it a rod may run up posteriorly, which, being curved at the top, will permit of the addition of a suspensory apparatus for the head, thus taking the weight of the head off of the spinal column, and tending to transfer it to the hips. A jacket thus made will stand almost any amount of ill-usage; it can easily be removed at night, or when desirable to perform ablutions, etc., and weighs but very little comparatively, a plain, leather jacket for a child nine or ten years of age weighing but about eighteen ounces. In those cases where it is desirable to place the lower limb in a fixed dressing, in order that a cure of a diseased joint may be effected by means of anchylosis, at the same time that it is desirable to keep up extension, and yet permit the patient, for the sake of his health, to be about, the following plan, which has already been suggested to the profession, can be pursued: The permanent dressing, no matter of what nature, having been applied to the diseased limb, is allowed to harden; a shoe having a cork sole, or an iron platform attached to the sole, being placed on the sound foot, the injured limb is thus permitted to swing free, making thus its own extension; by the aid of crutches the patient can then take the necessary amount of exercise to build up and maintain the stamina of the constitution. There is another apparatus, known as Barnes' wire splint, which, while the patient is in the recumbent position, may also be made to serve the purpose of a fixed dressing. In closing this paper I would beg to state that I do not consider that I have given all the forms of permanent dressings that have ever been, or are now employed, but I think the above list is one which will serve the purpose of summarizing the more commonly employed dressings used in surgery; and while none of the dressings here tabulated are decidedly new, yet there is a satisfaction in knowing that old things sometimes bear resurrection and rearrangement.

FRACTURE OF THE OS FEMORIS.

BY E. MICHENER, M.D.,
Of Sylvania, Pa.

Having had an experience of more than sixty years in the treatment of fractures, I am willing to note, very briefly, some of its results. My remarks will relate to the fracture of the os femoris. While I am aware that comminuted and compound fractures, and those occurring at the extremities of the bone, are exceptional cases, and may sometimes require an exceptional treatment, I shall leave them to the skill and ingenuity of the surgeon to make such modification as circumstances may demand.

Whatever may be the methods and the results in hospital practice, success in the treatment of fracture of the femur, in a country practice, appears to be the exception rather than the rule. This too general failure has become an *opprobium medicorum.* The result is, too generally, a shortened limb.

The inquiry then comes up, Why this shortening? And the ready answer is, From the difficulty of keeping up the necessary extension during the treatment. Some, perhaps many, claim that there must of necessity be a shortening in all cases of this fracture. I have, indeed, recently known of a city surgeon turning over volumes of surgery, to stop the murmurings of a limping patient by proving this necessary shortening. I do most emphatically assert that in ordinary fracture of the shaft of the femur there need be no direct extension made; and, further, that there can be no shortening if the bone has been properly coaptated and held in position. There has, indeed, been much spoken and written about oblique fractures of the shaft of long bones allowing the fragments to slide readily past each other. This, I opine, is a very rare occurrence. If we should break a hundred pipe stems, at least ninety-nine of them would be transverse and the remaining one doubtful. So, I apprehend, it is with the os femoris. It is difficult to conceive of a force that could produce an oblique fracture; and my experience is confirmatory. I have never met with an oblique fracture of a long bone, except one—a tibia; it was fractured by a heavy, crushing force.

In every fracture of the femur that I have seen, and they have been many, the bone, when coaptated, was itself sufficient to preserve the length of the member, without having recourse to direct extension. It is, indeed, too probable that many fractures of this bone have been pronounced oblique for no other reason than the failure of the operator to place the fragments in juxtaposition. It may safely be laid down as a rule, which has few exceptions, that so long as the bone fails to preserve the length of the limb, that failure is sufficient evidence that the bone has not yet been set. I wish very forcibly to impress this rule upon the attention of the reader.

There has been much dexterity employed; much mechanical ingenuity expended, in devising dressings for this fracture, without a corresponding result, owing, perhaps, to a misconception of what was really needed. In these cases the three great indications, the three imperative duties of the surgeon, are—

1. Most carefully to adjust the fragments.
2. To prevent their flexure or rotation.
3. To provide every possible comfort for the patient.

In some twenty-nine out of thirty cases, perhaps in a double or triple ratio, this is all that the surgeon need or can do. Such has been my experience.

1. *The Adjustment of the Bone.*—Very often the fragments will be displaced by the fracturing force, or other conditions of the injury. When the patient is laid supine, if the limb is either shortened or the foot rotated, there must be displacement. An assistant should make extension, very gentle at first, and slowly increasing it, so as to obviate, as far as possible, the pain to the patient and the resistance of the muscles; both of which are greatly increased by a hasty procedure. It may require five or ten minutes, or a half hour, but the muscles will eventually relax and permit the fragments to drop into place, sometimes with an audible click. While the extension is still kept up, or even increased, the surgeon should carefully manipulate the limb, until fully satisfied of the result. The extension should be slowly relaxed, as it was begun. If any displacement should remain, or the member be found shortened, the bone has not been properly replaced, and the same process must be repeated. As already intimated, the bone must be made to maintain the length of the limb. When there is very great muscular resistance, or suffering, an anæsthetic may be indicated. When the fracture is properly set, the muscles will hold the fragments closely together, if flexure and rotation are avoided.

2. *The Dressing of the Limb.*—This procedure can only be predicated on the method selected. But there are a few principles which may be introduced, and which, if they are not applicable to all methods, should serve to determine the method.

1. The injured member should be placed in a semi-flexed position. I have always used an angular splint (say 120° or 130°).

a. Because it places all the muscles which act directly upon the broken bone in a semi-relaxed condition, a state of repose the least tiresome, and the least liable to occasion spasms.

b. Because the position of the leg and foot, being pendent over the angle of the splint, effectually prevents any rotation of the lower fragment on its axis.

c. If from any cause a mild extension should be advisable, it is afforded by the angular splint, which, from its nature, becomes an *extensor*. The taper of the thigh inclines the dressings toward the knee, or rather, tends to draw the thigh out of them. The leg, resting upon the anterior plane of the splint, opposes this tendency; and to the same extent exerts a tractile force upon the lower fragment. Though not otherwise necessary, it may help to maintain a steady bearing of the limb. It is the only tensile force that I have ever used.

2. The dressings should be exclusively confined to the fractured limb. Its integrity should be made complete, by its own appliances; and yet be left free to respond to the necessary movements of the body. The movements of the body cannot be avoided, and it is well to allow the limb to move with it, in its entirety, as a whole, but never by sections. There seems to be unnecessary care taken to confine the whole man, greatly to his discomfort. I have generally allowed my patients to lie down, or sit up, in the bed, at their own pleasure, and have not found a bone displaced by their doing so. This brings us

3. *To consider the comfort of the sufferer.*—To the relief, so grateful to the patient, which even a slight change of position affords, may be added the ease with which the dressings can be readjusted, almost without waking a sleeping patient, and the facility with which he can be transferred to another bed. Children can often be soothed by placing them on the lap of a kind nurse.

I would again earnestly recommend:—

1. A more careful adjustment of the fracture than has too often been made, until it is found to fully maintain the length of the limb.

2. The propriety of securing the complete in-

tegrity of the whole limb, with freedom for it to respond to any necessary or accidental movement of the body.

3. The semi-flexure of the limb.

There may be various methods which would secure the specified conditions when judiciously employed. I can only refer to the method which I have used for a long series of years with good satisfaction to myself and to my patients.

Having, even while a medical student, lost confidence in the methods then in use, I very early accepted the views herein presented, and constructed an apparatus for fracture of the os femoris in accordance therewith. The only appliance that I have ever employed.

The Description.—The basis of the apparatus is a concave splint, cut across in the middle and united with hinges, and held at any desired angle by a binding screw. Both the ischiatic and the pedal extremities are made readily extensible for adaptation to different persons. At the foot there is a sliding standard, carrying a laced shoe, which can be raised and lowered at pleasure, both movements having binding screws. The edges of the splint have each a series of brass buttons, with leather straps to buckle over the limb.

The minor thigh splints are three in number; they are formed by glueing three strips of light wood on soft leather or canvas. The middle pieces have spuds on the upper side, to prevent their slipping endwise. A few folds of soft flannel, to pad the splint, and a bandage of strips, complete the essential dressings.

The Application.—Having adjusted the fracture and waited to know that there is not any retraction of the limb, then regulate the length of the upper section of the splint by the sound limb; apply the pad, and lay on the bandage strips. The limb may then be laid carefully on it (either straight or angular), the bandage and minor splints applied, and the straps securely buckled over them. If the splint was left straight, it may now be gently flexed to an angle of about 120°. The foot adjustment is easily completed. A similar bandage below the knee is some safeguard against spasmodic contractions of the muscles.

The patient is now tired, and a lunch is waiting in the dining room; let him rest. But, before going home, carefully inspect every part of the dressing, and if necessary re-adjust it, and give the needful directions to both patient and nurse.

The reader may call all this egotism. Perhaps it may be. But the surgery of fractures, especially of the os femoris, is so largely empirical, so often unsuccessful, that experience seems to be the only safe basis for prescriptive rules. I will only add, that I had my axes all nicely ground before I entered my eighty-seventh year.

Hospital Reports.

CLINICAL CASES—JEFFERSON MEDICAL COLLEGE HOSPITAL.

WITH REMARKS BY J. M. DA COSTA, M.D.,

Professor of Medicine and of Clinical Medicine.

REPORTED BY CHARLES R. CRANDALL, M.D., DECEMBER 6th, 1880.

Goitre.

The name of this patient is Mary E., and her age is nineteen years. She supports herself by carpet-weaving. For the last two years, such is her statement, she has had a growth in her throat. At times it is quite large, and then it seems to lessen in size, hence undergoing various changes. She is also a great sufferer from dyspeptic symptoms, and has nausea, vomiting and constipation—in one word, she has the symptoms of marked atonic dyspepsia. Associated with all of this, there has been some loss of flesh. When we look at her we are struck with her marked anæmic appearance. There is a general pallor, and also pale conjunctivæ, bloodless lips and a coated, flabby tongue. When we examine the swelling in her throat, of which she complains, we notice that there is a decided enlargement of the neck. This enlargement is evidently connected with the thyroid gland, and is somewhat tender to the touch.

Now, as there is often some form of heart affection connected with these enlargements, I will examine that organ. I find the motion rather rapid, the first sound distinct and the second sound more distinct than normal; but there are no murmurs. Placing my stethoscope over the enlarged thyroid there are well-marked transmitted cardiac sounds, but no murmurs.

She also calls my attention to some small swellings back of her ears. I find, upon examination, that there is some enlargement of the cervical glands. There is no history of malaria or any constitutional disease. I learn, upon inquiry of her mother, that the girl has a great deal of irregularity at certain periods.

I shall diagnose and treat the case to be one of goitre, and there are three possibilities as regards its nature and origin:—

1. It may be goitre due simply to enlargement of the thyroid gland.

2. It may be an exophthalmic goitre, connected with functional disorder of the heart.

3. It may be goitre owing to a general tendency to glandular enlargements, and depending, primarily, upon the great derangement of the digestive functions.

In discussing these possibilities, the practical point is for us to make our diagnosis between the first and second of the possibilities. I shall decide against this being a case of exophthalmic goitre, for the following reasons: Such a case, to have gone two years, would have shown much more disturbance of heart and of vision than we

have here. In exophthalmic goitre it is the heart that is primarily affected, and the disorder is followed by an enlargement of the thyroid. Furthermore, had this been a case of exophthalmic goitre there would have been great changes in the appearance of the eyeballs: they would have been enlarged and bulging, whereas, here, they are unchanged.

Another clinical point which I have been noticing for the last few years is that when I place my stethoscope over an exophthalmic goitre, I hear most marked murmurs both in systole and diastole. Indeed, I often hear, besides these, a sort of roaring, and I have come to rely on these observations as a test. Not finding such symptoms here, I must exclude an exophthalmic goitre.

Now, in favor of this being a case of goitre due to general glandular enlargement, and associated with ill nutrition, we have the history of atonic dyspepsia, the profound anæmia and the undoubted evidence of enlargement of the glands of the neck.

In this case, if we want to obtain success, we must resort chiefly to constitutional treatment. The remedy I want to give is the syrup of the iodide of iron; it is here preëminently indicated; but unfortunately it is not generally well borne by the stomach It is an excellent alterative in such cases, and we had better try it, at least. I will prescribe, therefore, twenty drops of the syrup of the iodide of iron, twenty drops of glycerine, and water sufficient to make a drachm dose. She is to take this, well diluted, three times daily, after meals. She needs, besides, a generous amount of food, consisting of meat, milk, oysters and stale bread. I would not advise potatoes or bulky food, for the object is to enable her to have solid foods of a digestible and nutritious nature. Locally, we will, for the present, do nothing.

Sciatica.

The next patient is James McC., who complains of pains along the sciatic nerve. They commenced last September, and have lasted ever since. The pain begins at the left trochanter and extends down even as far as the toes. He has been treated a great deal for this trouble, but has not received much benefit. Internally, he has taken freely, he says, of the salicylates, and also quinine and iron. Externally, he has been blistered, but that has also failed to give him relief. There is no history of specific disease. Nor is there any history of rheumatism, unless the sciatica itself be regarded as of a rheumatic nature. The pain is worse at night. There are times when he is comparatively free, but there is no entire day in which he does not suffer more or less. Hence, there are lulls, but no distinct cessation of pain. Motion, as he walks, is not much impaired. The seat of pain is in the region of the left trochanter and the parts are tender to the touch. Running my hand along the course of the upper part of the nerve, he winces. He has lost some flesh, is pale and has poor digestion.

As we have had a number of cases of sciatica recently, I will not go into this case to any extent, but will direct your attention to the methods of treatment.

As a general thing, cases like this yield readily to blisters, conjoined with the use of hypodermics and the usual internal treatment. This case does not, and, therefore, we must resort to other means. Having had such good results from the use of chloroform of late, we will again employ it. It will be given by hypodermic injections near the tender spots, as in the previous cases. Internally, I shall give the ammoniated tincture of guaiac, with iodide of potassium. It is a very disagreeable remedy to take, but it is one often of great value in obstinate cases like this. I would advise ten grains of the iodide of potassium in two drachms of the ammoniated tincture of guaiac, after we have used the chloroform hypodermically for a few days.

Now, here is another case of sciatica. The man is forty-six years of age, and has been a sufferer for a long time. Here the pains begin at the right sciatic notch and extend down the outer side of the leg. He can walk well, but not without pain. As he exposes his leg, there is evi dently some atrophy. The tenderness along the nerve is slight, and nothing like what it was in the other case. Here we shall also pursue the same treatment, as regards the chloroform. In these cases we use the spirits of chloroform, which is not as strong as pure chloroform. The strength is one part of chloroform to twelve of alcohol. The amount administered at each injection is about a syringeful. As a great deal of the success depends upon how the injections are made, I will have one given now in the presence of the class.

The injection of chloroform, a plan of treatment so ably advocated by Prof. Bartholow, must be made deeply, near the nerve and at the seat of the greatest pain. In this instance the painful spot is near the trochanter, and hence in the region of the gluteal muscles. Take the syringe and insert the needle deeply into the flesh. Inject slowly, then withdraw, and afterwards place the finger over the wound for a moment, to close it. Usually these injections cause a burning sensation for a few moments, but this man says it does not hurt him much, if any at all. We will repeat this injection daily for a few days and adopt no other remedy until a fair trial has been made.

Localized Chronic Peritonitis.

The next case is one of much interest, and the man comes from a distance for an opinion. His name is John H. M.; he is thirty-six years of age. Two years ago he noticed a lump, as he terms it, in his left umbilical region, which has gradually enlarged to its present size. He states that it was painful from the first, and I find that it is painful to the touch now. Pain has been a prominent symptom all the time. He says also that, at first, he thought the lump was loose, but of late it appears more fixed. Making further inquiry I learn that six weeks before this lump appeared he was thrown from a wagon and sustained some injuries. He says, further, that he has not lost flesh. At present his appetite is not good, he vomits occasionally, the bowels are loose, the tongue is slightly coated and red. The urine has been examined and the results are negative.

Now, let us proceed to investigate more closely. By palpating I find the tumor very tender to the touch; the tenderness is mostly in one spot and not in proportion to the size of the swelling. I perceive a certain amount of hardness at one spot, but it is also out of proportion to the general swelling. There is moderate dullness, but not as marked as would seem from the appearance of the parts. Fluctuation is perceived, but very distinct, low down in the abdomen: there is none at all in the upper part of the abdomen. Splenic and hepatic dullness are not increased. Auscultation with the stethoscope reveals the beating of the abdominal aorta, but without murmur or thrill, and without lateral pulsation. I direct the patient to turn over, and listening along his back, I find no murmurs.

There is swelling of his feet and legs, but not very marked. The patient says the swelling is worse at night. Having gone over the case, I will ask the class to make the diagnosis. In reply I hear suggested "omental cancer," "abdominal aneurism," "floating kidney," "local peritonitis," and "chronic peritonitis." It is evident that we have several views to choose from, and we will proceed to notice them in their turn. In an obscure case like this, it is necessary to think of all possibilities and then set aside one after another, by a system of exclusion. Let us set to work, then, and eliminate such views as are not justified by the symptoms revealed.

The first view mentioned was cancer of the omentum. This has in its favor such symptoms as tumor, pain, tenderness and history of injury. These points make the view one worthy of consideration, but I pronounce against it. My reasons for so doing are as follows: In the first place the man's nutrition is too good for one suffering from cancer. Had there been a cancer for two years he would have been much emaciated and there would have been evidence of cancerous cachexia. Again, if this were a case of cancer there would be a general dullness coinciding with the entire mass. But, as I repeatedly pointed out to you, there is not dullness corresponding with the general size of the swelling.

A second view is that of abdominal aneurism, and there are reasons in its favor. There is a tumor in the abdomen, pain, pulsation, good nutrition and a disturbance of the circulation, as shown by the œdema of the lower extremities. But, as against such a view, there is no thrill, and there is an absence of the marked pulsation which might be expected in a tumor of this size. Besides, the pains of an abdominal aneurism are usually felt in the back; they are sharp, fierce, and often shoot down the entire leg. Hence, owing to the absence of the proper physical signs, I must likewise decide against this opinion.

The suggestion of floating kidney also claims our attention for a moment. In favor of this view is the tumor, good nutrition and history. But, as opposed to such a view, the situation of the tumor is wrong; it is entirely too low down. A movable kidney would be away up, under, or just below the ribs. It would not be very painful, and there would not be the swelling as in this case. Therefore, we must dismiss this view.

Now we are brought to a consideration of the diagnosis of peritonitis, which is the correct one. This is a local peritonitis with some effusion, the result of an injury. The symptoms in favor of this are some fluctuation, great tenderness and a comparative absence of dullness, or, at least, of extended dullness. The fluctuation indicates some effusion into the peritoneal cavity, and also points to peritonitis. The œdema of the extremities is accounted for by pressure on the large veins returning blood from the lower extremities.

In point of treatment I would advise, locally, the iodide of lead and belladonna plaster, in equal quantities of each. If a plaster of this kind should prove too heavy, the ointment of lead and of belladonna may be used. Internally, I would suggest the iodide of mercury, with opium, say one-eighth of a grain of the former, and one sixth of a grain of the latter. The patient should be kept quiet in bed for a time. Under this alterant treatment we may hope to see rapid improvement. Subsequently, when the bowels are a little more under control, I will prescribe with a view of relieving the dropsical swelling and promoting absorption.

Periscope.

The Treatment of Insomnia.

The following suggestions are made by Dr. James More, in the *Practitioner*, Dec., 1880:—

During sleep the cutaneous capillaries are in a state of dilatation, so as to ensure that degree of cerebral anæmia which the physiologist tells us is a necessity to the presence of the "drowsy god." This flushing of the skin surface with blood, with its consequent cerebral anæmia, is fostered and provided for in the warm bed-clothes which the habit of ancestral civilized society has made almost an instinct, and stamped as a physiological necessity.

The physician, when called upon to prescribe for insomnia, meets with it in various aspects, but in a large number of instances it is due to direct or indirect hyperæmia of the brain.

He sees it in the disturbed circulation of the bilious or gouty old gentleman; in the anæmic girl or the plethoric matron; in the patient with cold feet, or in the one again with flushed face and throbbing temples. In each and all the fundamental condition of sleep—cerebral anæmia—is absent, and what is wanting is something that will unload the cerebral vessels of their surplus blood. The surplus may be due either to arterial hyperæmia, or to venous engorgement, and the skillful physician will follow the indication.

Dilate the cutaneous capillaries, and we withdraw the surplus blood from the surcharged brain to the skin. A glass of hot grog at bedtime, a foot-bath of hot water, with or without mustard, a bottle of hot water to the feet, may be all that is necessary to dilate and flush the peripheral arterioles. Such, in many cases, act as true, safe and scientific hypnotics.

Failing in this direction, we take to those remedies which the therapeutist tells us dilate the cutaneous capillaries; and foremost, and safest, and most reliable among these we name bromide of potassium. This, with a little tension help from digitalis, forms an almost certain sleeping draught in most of the above conditions. A draught as follows might be given:—

℞. Bromid. potass., gr. xxv
Tinct. digitalis, gtt. xv.

This failing, the addition of even so small a dose as one drachm of syrup of chloral hydrate will "make all the difference between success and failure." Of course, in many cases a slight anodyne effect is wanted to complete any special draught, and the addition of a few drops of chlorodyne or Battley's sedative, besides doing this, seems to accentuate or intensify the action of the vaso-dilators.

This was forcibly illustrated in the case of a patient I saw not long ago, where almost absolute sleeplessness had existed for some weeks, the result of mental excitement and worry. He had been taking as much as six drachms of syrup of chloral nightly, without effect, and viewing it clearly as a case of cerebral hyperæmia, I prescribed the following combination, which acted at once and with marked and decided effect:—

℞. Bromid. potass., gr. xx
Tinct. digitalis, gtt. xv
Syrup. chloral hyd., ʒj
Liq. opii sed., gtt. v.

We do not mean to aver that such a combination acted solely on the hydraulic principle, or had no decided neurosal effect on the brain cells, but what we hold is that its power in dilating the cutaneous arterioles, and thus providing for cerebral anæmia, is its chief *modus operandi.*

Anæsthesia by Compressed Nitrous Oxide.

We read in the medical *Press and Circular*, November 3: Dr. Blanchard has just published, in the form of a *brochure*, a complete description of the anæsthetic of Paul Bert (protoxide of azote under pressure), with an analytical *exposé* of all the operations in which it was used, up to the present. We find that seventy operations were performed under its influence, of which thirty-one were by M. Paul Bert, sixteen by M. Sabbé, two by Marion Sims, etc. In this number were comprised ablations of tumors, amputations, resection of nerves, reduction of luxations, fistules, and anal fissures, lithotomies, resections, ablation of fibroid tumors of the uterus, etc. As to the advantages of this method of M. Paul Bert, the first that Dr. Blanchard signalizes is the rapidity with which the anæsthesia is produced, and the complete absence of all excitement. Secondly, that once insensibility is produced, the man is so completely under its influence, that were it not for the breathing, which remains perfectly regular, he would seem as dead. This state can last half an hour or an hour without changing. During this time the blood preserves its red color and loses none of its oxygen; the heart beats with its usual regularity, and the temperature does not increase. Thirdly, that at the third or fourth respiration of pure air the patient returns immediately to sensibility and to *bein être.* The period, more or less long, of torpor, numbness and nausea, after the use of chloroform or ether, are not observed. However, it happens frequently that the patient returns to consciousness some time before insensibility has completely disappeared, but this, instead of being a drawback, is considered by M. Blanchard as an advantage, especially in operations on those parts of the face covered by the inhaling mask. It was thus M. Péau had been able to extirpate an epithelioma of the lip after the apparatus was taken off. Such are the advantages. As to the inconveniences attending this method, only one is considered of any importance, the difficulty of procuring a room *à l'air comprimé* outside of Paris or large towns. It is thus evident that in country practice or on the battle field this anæsthetic could not be employed.

Case of Hemorrhagic Diathesis.

The following good example of this is given by Prof. George Buchanan, in the Glasgow *Medical Journal*, November, 1880:—

The patient, a young man, aged twenty-four presents a strikingly anæmic appearance, and is so debilitated by protracted hemorrhage that he is quite confined to bed, becoming giddy if he sits up even for a short time. Four years ago he was admitted to the hospital on account of continued hemorrhage following the extraction of a tooth. The actual cautery was used on that occasion, and after a short residence he was dismissed apparently quite well. A few days later, however, a return of the hemorrhage occurred. Plugging with lint and perchloride of iron was resorted to, and it finally ceased. The account of the present occurrence is that, on the 29th of August last he had one of the upper left molars extracted by a dentist, to whom no mention was made of the previous troublesome hemorrhage; blood continuing to flow, a plug of lint and matico was applied, but with no very good effect. The plugs were renewed at intervals for a week, but failed thoroughly to control the hemorrhage. The patient then consulted Dr. Donald M'Phail, who, on September 5th cauterized the bleeding surface and plugged the cavity. This procedure appeared at the time successful, but on the same night oozing took place through the plug, and two days later the hemorrhage became more active, and continued intermittently for a week, when it stopped spontaneously After two days it again commenced; a gutta percha plug was now applied. and with good effect, but the gum by this time had become so tender that the patient could not endure the necessary pressure, and he was therefore advised to enter the hospital, which he accordingly did on the 18th of September. On the 21st chloroform was ad-

ministered, and Professor Buchanan removed the adjacent tooth and some dead bone in the neighborhood of the bleeding. The antrum of Highmore, which contained a considerable quantity of fetid pus, was then opened, a thick pyogenic membrane scraped out, the actual cautery applied, and the antrum stuffed with lint. In spite, however, of this very thorough treatment, the bleeding returned on the 26th, but was easily controlled by re-stuffing the antrum. On the 30th it again recurred. At this date subcutaneous injection of ergotine was begun, four grains being administered three times daily, as a rule, for about ten days, and afterwards less frequently. This appears to have had a good effect, as up to the date of writing (14th of October) there has been no return of the hemorrhage. During this period the plug was allowed to remain in the antrum, but ultimately it softened, and came away in shreds.

Recent Views of Evolution.

In a recent address by Prof. Cleland, Professor of Anatomy in the University of Glasgow, he observed that while the experiments of Pasteur and Lister conclusively proved that there was no such thing as spontaneous generation in the present, the difference in character between development and the laws of matter made spontaneous generation an inadequate hypothesis to account for the first appearance of life in the past. After dealing at some length with the various arguments that had been adduced in reference to this theory, Professor Cleland said it was a legitimate position to take up, that all the evolutions of nature were definite, but that the series of such evolutions were indefinite in number and kind; that individual evolutions, like other individuals, were finite, but formed members of a larger total. So, in the evolutions of organization we saw vortic units, the textural elements, receiving and rejecting currents of material, while they maintained during a finite lifetime their individuality, and these united into larger individuals subject to the same law. In the evolution of vegetation, which everywhere exhibited definite individuals, or organs, structurally united in indefinite series, the highest groups were composed of compound individuals in whose structure the most complex, and in every way highest, evolution occurred in connection with the highest vegetable function, the perpetuity of the series of finite individuals; and, the flower once perfected, evolution had ceased, though variation continued. The largest feature in the evolution of both plants and animals consisted in that which was simple passing into the manifold, and the manifold being compacted together in a higher unity. And however imperfectly zoologists might yet agree as to the evolutions in detail in different parts of the animal kingdom, it was plain that in the human form an organism had at last appeared constituting an abode of intelligence such as existed in no other, and that in man alone intelligence reached the capability of ascending beyond the wants of the physical organism in the contemplation of abstract truth. That organism had not improved with the progress of discovery in modern science, but was, at least, as complete in the heroes of antiquity as in those of recent times. It was surely, then, an assumption to suppose that evolution as distinguished from variation in animal form must go on unchecked till astronomic change shall have ended the capability of this world to support life. It was far more probable that the evolutions of the future were to be sought in realms with which the zoologist acknowledged he had nothing to do, and take origin out of the special psychical characters of man. For his own part, he maintained that the universe presents an endless unrolling of definite evolutions, and that the evolutions of organization were completed, though its variations continued, while other evolutions were at work, and more would appear.

Ear Disease Following Scarlet Fever.

The London *Medical Times and Gazette*, Oct. 30, gives the treatment of Dr. Merian, of Basle. He holds that the best preventive of aural mischief in scarlet fever is the arrest of the primary diphtheritic process in the pharynx. He therefore cauterizes all patches that can be discovered, at first twice, and afterwards once a day, with a ten per cent. alcoholic solution of salicylic acid. A piece of cotton-wool of the required size is wound round the end of a small knitting-needle, on which a double screw is cut, and the wool, soaked in the liquid, is gently pressed on the part. Some pain is caused, but it does not last long. Nausea is best combated by ice, and the taste of the spirit can be concealed by adding one or two per cent. of oil of wintergreen to it. For the back of the soft palate, and for the pharynx, curved instruments are, of course, required.

The second preventive measure is the use of the nasal douche once a day, where the patient is intelligent enough to bear it. Following Tröltsch (*Archiv für Ohrenheilk.*, Bd. IX, S. 191), Dr. Merian provides a printed form of directions for its proper manipulation. The apparatus consists of an Esmarch's irrigator, with a tube two feet long, furnished with a glass nose-piece. A litre of warm water, in which seven and a half grams of common salt have been dissolved, is the liquid employed at first. Without the salt the water irritates the nares. Later on, one or two tablespoonfuls of salicylated spirit are added to each litre. It is very important that the douche be slowly administered, the patient breathing quietly with open mouth, and not speaking or swallowing. The irrigator must not be raised more than one foot above the level of the head, else water may easily enter the Eustachian tube and penetrate the ear, giving rise not only to pain, but possibly to tedious inflammation. Besides the douche he recommends gargling every two or three hours with a dessertspoonful of salicylated spirit in a small glass of water, and the application of an ice-bag to the front of the neck from one mastoid process to the other. Pieces of ice are also allowed to dissolve in the mouth, but the patient is told to spit out the water formed from it. Very small children are excited to sneeze, and so temporarily clear their nares, by a snuff of pure salicylic acid, which for infants may be diluted with equal parts of starch powder. Before leaving the subject of prophylaxis, Dr.

Merian mentions that it has seemed to him that consecutive ear affections have been most often met with in cases of scarlet fever treated by cold baths or the cold "pack," both of which tend to cause congestion of the head.

In treating the acute stage of the otitis itself he uses ice externally, protecting the very sensitive lobe of the ear from the cold by flannel or a piece of wadding. The pain is relieved by iodine paint, or by iodoform ointment (iodoform, ol. fœniculi, āā 1.0 gram, vaseline 8.0), covered with gutta-percha tissue, and over it the ice-bag. Very severe pain yields to equal parts tinct. opii and water, ten to twenty drops being poured into the meatus. The intermittent pains occurring toward evening or by night, and which are very depressing to the patient, require quinine (0.20 to 0.50 gram) internally.

As soon as the acute stage is over, air should be blown into the tympanic cavity with a Politzer's bag, to restore the equilibrium of the internal air with the external atmosphere, and allow the membrane, which has yielded to external pressure, to recover its position. If, however, in spite of these measures, the fever continues, the mastoid process is tender, and dull pain is felt over the whole head, paracentesis of the tympanum is indicated. The opening made should not be too small, and there is generally rapid relief after the operation. The escape of secretion from the middle ear should be aided by Politzer's bag. Syringing should be avoided the first day, and wadding, frequently changed, alone used to soak up the discharge. The patient is ordered to lie on the side of the affected ear; and if, as often happens, great improvement follows the puncture, iodine and ice alone suffice for the cure. If, however, the discharge is copious and with difficulty checked, the ear is syringed with a five per cent. solution of sodic sulphate, which Dr. Merian has long preferred to all others for this purpose. The wadding he uses is boracic. The very destructive diphtheritic forms of otitis media require the membranes, which often fill the whole osseous meatus and obscure the tympanum, to be scraped away energetically with a curette or removed by a "Wilde's snare," and the parts to be dabbed with salicylated spirit, or dusted with pure salicylic acid; the ear must also be syringed several times daily with diluted salicylated spirit (one to two dessertspoonfuls to 100.0 grams water). These proceedings are rather painful, but generally wonderfully efficacious. Profuse suppuration in these latter cases, without fever, is best treated by thorough syringing twice a day, either with diluted salicylated spirit, carbolic acid (acid. carbol., sp. vini, āā. one dessertspoonful to 100.0 grams water), or boracic acid (one to two dessertspoonfuls to water Oss). By the adoption of these measures at the outset, Dr. Merian is convinced that the number of cases of chronic ear disease after scarlet fever will be much reduced, as well as the danger to hearing and to life which is its too frequent consequence.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

OUR EXCHANGES.

——*St. Nicholas*, for December, the Christmas number, came a little late, but is so beautiful and such a delight to the "young folks," that we were well repaid for its delay.

There is nothing to compare with this charming magazine for children, in the country.

The Sunday School Times is one of our best valued and most regular exchanges. It is unsurpassed, as a valuable aid to the Sunday School teacher, and for home study of the Bible lessons of the year.

The January number of *Scribner's* contains an account of the aims and methods of the new Horological and Thermometrical Bureau recently established by the Winchester Observatory of Yale College, from careful personal inspection on the spot. This is the first bureau of the kind established in this country, and cannot fail to raise the standard of excellence in both clocks, watches, and thermometers. The curious machinery used to correct watches to the tenth of a second, together with some singular facts in the behavior and habits of thermometers, make the article of more than usual interest to the reader. The same number also contains some account of Mr. John La Farge's and Mr. Louis C. Tiffany's recent work in stained glass.

The January number of *Lippincott's Magazine*, which opens a new series at a reduced price, presents itself in an artistically designed cover, that at once attracts and pleases the eye. This favorable impression is more than confirmed by an examination of the contents, which are generally light and of a thoroughly popular character, while marked by literary excellence of a high order. The illustrations, too, are carefully executed. The new arrangement of the editorial matter cannot fail to prove attractive, and altogether the number is full of promise.

——In an address before the American Academy of Medicine, Dr. F. D. Lente gives some stirring words in favor of the higher education of medical men. Published by Bermingham & Co. New York.

——Dr. H. Wardner's Essay on "State Medicine," before the Tri-States Medical Society, has been reprinted, and may be had of the author, Anna, Illinois.

BOOK NOTICES.

Proceedings of the Alumnæ Association of the Woman's Medical College of Pennsylvania. 56 pp.

This unpretending volume cannot fail to be read with interest. It is one of the first which owes its origin to the female physicians of this country as a body—so far as we know, actually the first.

The Proceedings are principally made up of reports of cases in gynecology. There is, however, an address on dysmenorrhœa, by Dr. Anita E. Tyng. She attacks the theory that it is usually the result of constricted cervix; believes that it is most frequently caused by spasmodic and painful contractions of the muscular fibres of the uterus. She adds, we think very justly—

"This theory serves as a warning against the so-called forcing medicines. I have observed that the most robust women have, comparatively, a small quantity; delicate ones menstruate more abundantly. I, therefore, deprecate all medicines for increasing the quantity of the menstrual fluid, except where some nervous or congested condition demands that relief. It seems to me that the theories of spasmodic muscular contraction I have quoted account for this want of relation between quantity of fluid and size of the os. Statistics are wanted as to the nervous and other bodily conditions of the patient in cases of dysmenorrhœa; this is apt to be left out of the reports of cases. There is too great a tendency to treat the uterus only and forget to treat general symptoms. I have had success in several cases by general treatment only, leaving the uterus untouched."

Several cases of ovariotomy are given, and Dr. Romania B. Pratt sends a very instructive medical report on Utah Territory. Of the diseases of that Territory she writes:—

"As I scan the table of death, the monthly mortuary of Salt Lake City, for 1879, I observe the deadly footprints of the epidemic of diphtheria. The total number of deaths from this disease in 1879 was 156, the greater number under ten years of age. I find the next greatest fatality in acute lung diseases; pneumonia 50, bronchitis 5. It is said that this region of country is peculiarly favorable to the recovery of patients suffering from phthisis pulmonalis, if destruction of lung tissue is not too far advanced. The report gives ten deaths from this disease. I will mention the fact—interesting on account of its negativeness—the record of one death from syphilis. I have not met with a case yet in my practice."

Cases of ovariotomy, tonsillitis, perineoraphy, pelvic hæmatocele, ventral hernia, etc., are recorded.

The attention of the Association was called to a new leather splint, the invention of Dr. Cynthia Smith, which had been submitted to the managers of the Woman's Hospital, with an application for the prize offered by that body for original inventions of surgical appliances. It was examined by the members present, and pronounced an original and useful invention.

A Practical Treatise on Diseases of Women. By T. Gaillard Thomas, M.D., etc. 5th edition. Philadelphia, H. C. Lea's Son & Co., 1880. Half Russia. Price $6.50.

It is superfluous to enter into any detailed examination of this well known and standard production. The present edition appears after a thorough and careful revision on the part of the author. He tells us in the preface that he has devoted two years of labor to the endeavor to render it all that it should be, in view of the rapid advances made in this active department of science. The marks of this labor are evident in almost every chapter of the book; and it may be said to be as good a presentation of gynecology—as complete and as exhaustive, considering its limits—as any which is to be found in any language. Of course, it has not the fullness of Billroth's great enterprise, but as a text-book it is superior to it.

We must not omit to mention the beautiful style in which it is bound—in half Russia. The publishers inform us that in order that the taste for fine binding may be encouraged, the prices have been fixed at so small an advance over the cost of sheep as to place it within the means of all to possess a library that shall have attractions as well for the eye as for the mind of the reading practitioner. That safety in carriage may be insured, each volume, wrapped in soft paper, is enclosed in its individual box.

A Manual of Medical Jurisprudence. By Alfred Swaine Taylor, M.D., F.R.S., etc. Eighth American Edition. By John J. Reese. Philadelphia, H. C. Lea's Son & Co., 1880. Half Russia. Price $6.50.

The long and successful life of this mannal speaks abundantly for its merit, as well written, oft revised and ably edited. The author is now deceased, and among his latest labors was the preparation of this edition for the American profession. His additions, together with the notes and commentaries contributed by Dr. Reese, bring the work quite up to the most recent progress in this particular branch. Although written originally for the horizon of England, most of the matters discussed belong to science and to common law, and are quite as well adapted for instruction in the United States as in Great Britain. There are also notes by Judge Penrose, which further render the work American in tone.

This is one of the volumes which the publishers put out in half Russia binding. It is very neat, and cannct but prove durable and popular. The cost is so little that it is well worth the difference.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

WHY BE A DOCTOR?

There are about a thousand young men in Philadelphia, this winter, preparing themselves to practice medicine. There are as many more in New York city, and again as many more in other cities within the limits of the United States.

Statistics and daily observation indicate that the physicians in this country are increasing in proportion to the population; in many cities they already number one to every five hundred inhabitants.

What is it that leads so many young men to adopt the profession of medicine? It will be a fruitful inquiry if we can analyze their motives.

It is not an easy profession and it is not a lucrative one; it is rather expensive to learn, and involves moderately hard study. The average income must necessarily be small, when, as above stated, the hundred families (allowing five persons to a family) are all the *clientèle* that the average doctor can expect.

As an avocation it is a very respectable but not a very profitable one. One of the New York newspapers remarked, at the last meeting of the American Medical Association, that such a large body of intelligent men, *representing so little capital*, could not be found in any other business or profession. Plenty of doctors do not average, year by year, in solid money, from their practice, more than two thousand or twenty-five hundred dollars a year, and consider themselves lucky with that; plenty fall far short of that.

Archbishop Whately pointed out, with reference to the Church of England, that its attractiveness was not the ordinary salaries, which were too low to repay men of ability, but the chances for a bishopric with ten thousand pounds a year. The great prizes are what tempt those who invest in a lottery. So it is with our profession. There are a few men in it whose practices are worth $25,000 to $50,000 a year; a *very* few who can beat that. Hope whispers her flattering tale in the ear of the ardent youth, and he has not yet learned enough of the vanity of human expectations to doubt her siren voice. He thinks he, too, may attain this first place.

Another reason is, our profession *requires no capital*, or very little. The graduate, furnished with his sheepskin, is at once prepared to do all that opportunity offers to his hand. He has completed his investment in obtaining his education. This is unquestionably a powerful inducement with many, and one which leads them toward the professions rather than toward mercantile pursuits.

Some are led to medicine because it appears an *easy* way of making money. The doctor calls, chats a few minutes, scribbles a few lines on a bit of paper, drives away, and sends in a bill for two or three dollars. This seems so marvelously easy to the imagination of the hard-working classes that the temptation is strong to save enough to put one of the boys at a medical college. How illusive the appearance is we need not say to the readers of this publication.

The above are the less noble motives which prompt to enter our profession, but probably the more common ones.

There are young men influenced by something better. A few are impelled by the desire to

lead a useful life, directed toward the alleviation of the physical suffering of their fellows; a few are born physicians, and occupied themselves as boys with such matters, liking to help in sickness, and to read medical books.

There is also the scientific spirit, which is now widespread, the desire to investigate the order of nature, which finds its satisfaction more in the medical than in most other recognized businesses. Prof. J. Burdon-Sanderson, the distinguished physiologist, touched happily on this instinct in one of his recent addresses:—

"Although medicine," he said, "as an art has grown by the slow accumulation of experience, it has, since it arrived at maturity, given birth to a science the purpose of which is to investigate the origin and nature of disease. This science we call the science of medicine, or pathology. The problems which it offers possess interest enough to make them attractive to all truth-seekers—an interest which is increased rather than diminished by the fact that the amount of knowledge which as yet exists as to the way in which the human body is acted on by its surroundings so as to produce disease is very scanty. We may confidently hope that before another twenty years have passed there will be a great increase of this knowledge, for, at the present moment, the systematic investigation of the nature and causes of disease is being carried on with unprecedented activity, and we have the satisfaction of seeing even the darkest corners of the subject one after another made accessible to the 'dry light' of science. The cause which has determined this tendency to progress is not far to seek. Pathology is being carried forward by virtue of its association with other branches of physical science. To our predecessors of a generation or two ago, the notion that the suffering human body is subject to the same laws as those which regulate non-living matter, and that all our ailments are themselves the products of agencies which come within the cognizance of the chemist and physicist, seemed inadmissible and almost revolting. Now we have learned that, in so far as we understand the processes of life, whether healthy or diseased at all, we get at this understanding by comparing them with better-known processes which present themselves to our observation in the world outside of us. It is on this principle that all researches as to the origin and nature of disease must, if they are to lead to permanent results, be founded."

Would that the spirit which imbues these lines were more generally diffused. As it is, there are exceedingly few physicians who, after they enter practice, continue their profession as anything more than a means to gain money and social reputation. Had they commenced its study from more elevated motives, they would make these considerations secondary to others; and were such motives more common with students, the relations between practitioners would be more harmonious than is generally now the case.

THE BACILLUS AS THE SOURCE OF ANTHRAX.

It was supposed to be a great discovery when microscopists announced the presence of the *bacillus* in the blood of animals with anthracoid diseases. The organism was received as the undoubted cause of the malady. But further researches throw serious doubts on this view. H. Buchner, and later, Prof. A. P. Fokker, of Göttingen, have shown conclusively, not only that there are varieties of malignant anthracoid disease in which the bacillus is not found in the fluids of the body, but they have proven that there is absolutely no difference at all—at least, none that can be detected by observers—between the so-called *bacillus anthracis* and the innocent *bacillus subtilis* found in any infusion of hay (*Centralblatt f. Med. Wiss.*, Oct. 30).

In fact, this and other facts which have been laid before the profession go more and more to show that neither bacilli, nor bacteria, nor micrococci, nor any other of these low organisms whose presence can generally be detected in the pathological secretions and in the fluids of the body when diseased, have any direct etiological relation to the diseases present. They are there, as are maggots in putrefying flesh, not as cause, but as result of the death or degradation of vital action.

There is a perceptible tendency visible within the last year, to go back to a chemical hypothesis to explain the etiology of epidemics. Spores and germs are not so popular as they were. Even the specific organisms of particular diseases are not on hand always when they ought to be, to support the theory of their *raisôn d'être*. Last spring Dr. R. Albrecht announced, in the St. Petersburg *Med. Wochenschrift*, that after long search in two cases of relapsing fever he could only find three examples of spirochæta obermeieri in the blood. After the preparation had been left for six hours the number of these bac-

teria had increased, several being visible under the microscope in each field, and all moving actively. During the remissions the blood was examined daily, no organisms being at first visible; after the preparation had been left for some days in a moist chamber, however, they suddenly showed themselves at a somewhat later period than would correspond to the patient's exacerbations, and they appeared to develop somewhat more slowly in the preparation than in the living blood. Dr. Albrecht noticed that the spirochæta did not disappear after the death of the patient, for he found them in large numbers in the corpse, though they were motionless.

It is worth noting, that Dr. Jacobi, in his recent monograph on diphtheria, substantially renounces the theory of infectious germs, and takes his position among the believers in a chemical contagium.

Notes and Comments.

The Relation of Sexual to Cerebral Activity.

Some sound remarks on this point occur in an article of Dr. Skene's, in the *Annals of the Anatomical and Surgical Society of Brooklyn.* He says: The effect of impertect sexual organs upon the brain and nervous system is perhaps greater than upon the nutritive system. The sexual appetence exerts a marked influence upon the development of the brain and nervous system, and also upon their functions, by exciting the exercise of the intellectual faculties and the emotions in a variety of ways. Many of the manifestations of the mind are but responses to extrinsic impressions and physical wants. During early life—the "receptive age," as Dugald Stewart called it—the brain is called into action by surrounding objects and whatever there is outside of itself that can affect it; therefore mental development depends largely upon the impressions made upon it. By withholding the influence of the sexual organs, a modified mental condition is the sure consequence, and that modification is toward a lower organization. The facts obtained by clinical observation support this doctrine. Among the insane I have found a number of young patients in whom the sexual organs were imperfect and inactive, and the brain was correspondingly defective. They were normal as children, but they remained childish. The arrest of brain development apparently took place at puberty, and deranged function in the form of insanity followed soon after.

Explosive Pharmaceutical Combinations.

The *Bulletin de Therapeutique*, Oct. 1880, gives several combinations in pharmacy which are liable to explode, and as patients complain so often that they are liable to be "busted" by doctors' bills, we quote these dangerous compounds lest they more literally be "busted" by doctors' pills.

1. Hypophosphite of lime, chlorate of potash, and lactate of iron, when mixed in the dry state, explode violently.

2. A solution of four parts of chromic acid in eight of glycerine also explode.

3. Chlorate of potash, mixed with a dentifrice, in the form of a dry powder, and used with a dry brush, will give rise to explosions even in the mouth.

4. Pills composed of permanganate of potash and extract of yarrow, or of the same salt with reduced iron, or of sulphureted antimony and chlorate of soda, are apt to deflagrate during or after preparation.

It follows from these facts that glycerine, and, in general, all such reducing agents, should never be combined with oxidizing agents, such as chromic acid, the chlorates, permanganates, and certain organic acids.

Quinine for Hypodermic Use.

It is stated in the *Practitioner*, Nov., 1880, that for hypodermic use Prof. Köbner considers that the hydrochlorate of quinine is best suited, not only on account of its greater solubility, but because it contains a larger proportion of the base than does sulphate of quinine, while the solubility of the preparation is greater in pure glycerine than in water. Thus, Prof. Köbner has obtained as good results in cases of intermittent neuralgia and other affections for which quinine is usually prescribed, from the injection of 0.12–0.15 gram. of quin. muriat, as are ordinarily obtained from the administration by the mouth of much larger doses (0.6–1.25), while the patients did not complain of any constitutional or gastric symptoms. The author gives the following as his formula for four injections:—

℞. Quiniæ. hydrochlor., 0.5–1.0
Glycerinæ.,
Aq. destill., āā 2.0.
Disp: sine acido.

Who First Investigated Neurasthenia.

As he who deserves it should carry the palm, according to the Latin proverb, we give the benefit of our circulation to the following statement of the editor of the *Alienist and Neurologist*, in his October issue :—

To an American superintendent and physician of a hospital for the insane is due the credit of having first, in this country, clearly pointed out and differentiated neurasthenia from other diseases. The name of that physician is Dr. E. H. Van Deusen, of Kalamazoo, Michigan. In a supplement to the biennial report of the Michigan Asylum for the Insane, for 1867–8, under the caption of "Observations on a Form of Nervous Exhaustion (Neurasthenia) Culminating in Insanity," he wrote as follows: "Our observations have led us to think that there is a disorder of the nervous system, the essential character of which is well expressed by the term given above, and so uniform in development and progress that it may, with propriety, be regarded as a distinct form of disease." In this instance, as in many others, the medical superintendents of the hospitals for the insane, in this country, have anticipated the profession outside of them in important contributions to clinical medicine.

Hot Water for Sweaty Feet.

In an article in the Ohio *Med. Recorder*, Dec., 1880, Dr. Pooley says:—

Dr. Gay, of Columbus, informs me that when he was at the Hot Springs, in Arkansas, he saw there what was called the "corn hole," being one of the hot wells for which the region is celebrated, in which numerous persons were in the habit of soaking their feet for many hours every day, until their corns were thoroughly macerated, and could easily be pulled out by the roots. He was told that it also cured sweaty feet, which he found, on inquiry, to be the fact, and since his return home he has cured this affection in many instances, by simply directing the feet to be soaked, for hours every day, in water as hot as can be borne.

The Metric System in Machine Shops.

In the November number of the *Journal of the Franklin Institute* is a strong article by Mr. Coleman Sellers, showing why the metric system should *not* be introduced into American machine shops. His arguments are conclusive, and we recommend them to the perusal of the metric fanatics. They apply in a great degree to dispensing pharmacy, as well as to the manufacture of machines. His comments on the conflict of meteorological systems are acute, and sufficiently indicate the difficulties which stand in the way of any harmonious action.

There is no doubt but that the more closely the metric system is scanned and tested by practical men, the less does its introduction recommend itself. Shall it not be dropped altogether?

Wickersheimer's Fluid.

As we have been requested, several times, to repeat the formula of this preserving fluid, we do so here, the more readily, as the original formula has been gradually somewhat altered, so as to facilitate its manufacture, and to make it better applicable for various purposes. Messrs. Poetz and Flohr, of Berlin, prepare two kinds, one intended for injections, the other for macerating and immersing bodies, etc. Their composition is as follows:—

	For Injecting.	For Immersing.
℞. Arsenious acid,	16 grams.	12 grams.
Sodium chloride,	80 "	60 "
Potassium sulphate,	200 "	150 "
" nitrate,	25 "	18 "
" carbonate,	20 "	15 "
Water,	10 litres.	10 litres.
Glycerin,	4 "	4 "
Wood-naphtha,	¾ "	¾ "

Means of Treating Inflamed Hemorrhoids.

The treatment used by M. Chéron, *Revue Medico-Chirurgic.*, to combat congested and engorged states of the uterus, is based on the exosmotic properties of glycerine, and consists in the use of vaginal suppositories of this substance, rendered solid by the addition of a small quantity of white glycerine. M. MacAuliffe, in the *Journal de Med. et Chir. Pratiques*, having often obtained good results from this method of treatment, had the idea to use the same application in inflamed hemorrhoids. He prescribed suppositories containing:—

℞.	Glycerin,	3 parts
	Gelatine,	1 part
	Ext. bellad. vel opii,	gr. ss.

The gelatine is melted in the glycerine, and suppositories are obtained of sufficient consistence for introduction into the anus. The result of this medication surpassed his expectations; a notable amelioration was observed after the first application, and three generally sufficed to dissipate the inflammation.

The suppository should be as deeply introduced as possible; in about an hour after the patient experiences a desire to evacuate the

bowels, and the first stool is liquid; this results from the affinity of glycerine for water, and this exosmotic action being exercised through the mucous membrane covering the hemorrhoidal tumors, produces their depletion.

Revulsive Applications in Tuberculosis.

Prof. Peter, in *l'Union Médicale*, makes the following recommendations:—

If the patient is still robust, cups or even leeches may be applied on the thorax, over the points where there exist signs of pulmonary congestion. If the patient is already enfeebled, it will be better to have recourse to dry cupping, sinapisms, and to flying blisters. Applications of croton oil, of thapsia, of plasters containing tartar emetic and Burgundy pitch, should be absolutely rejected, as they leave indelible marks. If the lesions are more advanced, an issue may be established by means of Vienna paste in the second or third intercostal space, about an inch from the sternum. If the patient should object to a permanent issue in one place, a second might be established just before the cicatrization of the first, and thus a revulsive effect be continuously obtained. Finally, the surface of the thorax, under the clavicles, may be lightly touched in twenty or more points, with the actual cautery, every five days.

The Elastic Ligature in Surgery.

Dr. Charles Simon has studied (*These de Paris*, No. 562, 1879), under the direction of Prof. Duplay, the elastic ligature and the advantages to be obtained from its use in surgical therapeutics. He considers its mode of action in anal fistula and in phimosis; he shows that by ligation with elastic substances the ablation of tumors of the tongue may be brought about, this method having been in practice by MM. Delens and Duplay. In inversion of the uterus also, this means may be brought into requisition, as also in spina bifida and mammary tumors. The conclusions arrived at by the author of the thesis, are: 1. The elastic ligature exposes less than any other process to the ordinary complications of operations (erysipelas, abscess, hemorrhage). 2. The elastic ligature is especially indicated in anal fistula, tumors of the tongue, uterine inversion, and for ligation of the umbilical cord, when enlarged and gelatinous (Budin). 3. The other uses to which the elastic ligature has been put cannot, as yet, be definitely judged.

The Spontaneous Cure of Phthisis.

Prof. Bennett, of Edinburgh, used to teach that a large percentage of phthisical cases recovered with ordinary care; Prof. Flint has advocated a similar view; Prof. DaCosta, we believe, thinks only two or three per cent. thus recover. Dr. Heitter, of Vienna, in the *Medizinische Jahrbücher*, 1880, recently gave the results of his investigation on this head into 16,562 post-mortem examinations. Of these, excluding cases where only adhesions or cicatricial retractions were found, there were 780 where centres of obsolete tubercle were found in the lungs, death having resulted, not from tubercle, but from some other disease. Of these 780 cases, 503 were males, 277 females, the numbers being tolerably equally divided between the ages of twenty and seventy-five, two cases having reached respectively 101 and 103 years! The individuals belonged almost exclusively to the working classes. The lung affection appeared mostly as black pigmented cicatricial tissue enclosed by gray-yellowish nodules, or cavities of size between a hazel-nut and a hen's egg, with more or less fluid contents. In 651 cases the disease was double, and in almost all it was confined to the apex. A spontaneous cure, he believes, takes place far more commonly in chronic than in acute tuberculosis; and so long as the tuberculosis has not extended beyond the upper lobe, a complete recovery is possible. If it has extended beyond the upper lobe, while cessation of the process for a longer or shorter time may take place, complete recovery is impossible.

Can Syphilis be Spread by Vaccination with Human Virus?

This subject has been vigorously discussed in various medical societies lately. For example, at the last session of the Rhode Island State Medical Society, last month, Dr. T. W. Perry read a paper on syphilis, with numerous clinical illustrations from his own practice. The discussion following this paper led to another subject, viz., the possibility of communicating contagious diseases by vaccination. The speakers were unanimous in the opinion that vaccine virus produces nothing but a vaccine pustule, and transmits no infectious disease. Care must be taken, however, to obtain pure lymph, on the eighth day, and to avoid its contamination with blood or cutaneous secretions. In point of fact, such care is never exercised, and it is next to impossible that it should be; hence the freedom from danger of syphilitic contamination is theoretical only.

The Treatment of Orchitis and Epididymitis.

The London *Medical Record* states that Prof. Wertheim recommends, in cases of moderate severity, besides rest in the horizontal position and support of the scrotum on a pillow placed between the thighs, the application of freshly spread mercurial plaster, which is to be changed every night and morning. If the swelling be very great, and the scrotum shining, and if great pain be present, ice-cold poultices are indicated. In case of abscess, the author makes a single incision, and does not use drainage-tubes, but syringes out the cavity twice a day with carbolic or other suitable lotion. When suppuration is too profuse, a lotion of sulphate of copper is to be used. The emplastrum hydrargyri may be applied at the same time, an opening being made in the plaster to correspond with that of the abscess.

Hint for the Use of the Actual Cautery.

Dr. John M. White, of Alabama, forwards us the following note, which will be of considerable value :—

In using the actual cautery, anoint the tissues around the place to be cauterized with liquid storax, and it will prevent them from being burned. In cauterizing the os always anoint the vagina with liquid storax and the vagina will not be burned.

Correspondence.

Congenital Hydrocephalocele or Craniomeningocele.

Ed. Med. and Surg. Reporter:—

December 3d, 1880, during the first heavy rain of the season, I was sent for to visit a babe eight miles northwest of this city. The messenger, not having seen the child, could only say that it had a large tumor on the back of its head. I arrived at the house during the early part of the afternoon, and learned from the midwife, who appeared to be an intelligent woman, that she had delivered Mrs. K., aged twenty-eight years, of her seventh child, about seven P.M., of the previous day. It having been a foot presentation she noticed nothing unusual until the head was expelled, which was not more than two hours from the time the mother felt her first pain, but "the waters having broke the evening before" she was on hand, expecting the confinement. The babe, a boy, weighed about eight pounds and was well developed, excepting the head. In size the latter was in proportion to the body, but the forehead began to retreat immediately above the eyebrows; the fontanelles were less than usual, but the bones were not united. Passing over to the occipital region I found a tumor resembling that of a bifid spine. At first I regarded it as an enormous craniomeningocele (Gross), but upon closer inspection I found that the upper portion of the sack contained a solid or semi-solid substance, and that it protruded from a fissure in the centre of the occipital bone, forming an irregular circle about one and a quarter inches in diameter, which changed my diagnosis to that of hydrocephalocele. By careful manipulation I was able to return the solid contents, with a portion of the liquid, into the cavity of the skull, which in reality reduced the tumor to a craniomeningocele. Up to this time the child had been in a stupid or semi-comatose condition, only crying when disturbed, and swallowing when milk or water was put into its mouth. These, with its labored breathing, were the only evidences of life. But now the eyes opened and the milk was taken with a relish. The lower portion of the tumor being deficient in true skin, a portion of the liquid had escaped through a rupture in the sack, during its passage through the maternal pelvis, and disintegration of tissue having set in at this point, I determined upon an immediate removal of the pendulous portion of the scalp and membranes. Placing the child upon a table suitably prepared, and otherwise being ready, my only assistant, the midwife, raised the tumor (in the condition before described) and I ligated it close to the head, then severed it about three-quarters of an inch from the ligature.

Knowing the almost certain fatal results of ligating the envelopes of the brain, I carefully and closely sutured the scalp and removed the ligature. No serum escaping I applied a light compress and instituted carbolized water dressing.

The sack was essentially composed of the scalp and the membranes of the brain, and contained three ounces of bloody serum. The tumor, as removed, weighed ten ounces, and in circumference, measured eleven by eleven inches.

When I left the house, two hours later, the child appeared to be in as good a condition as could be expected, but it survived the operation less than two days, dying, as I am told, in a convulsion.

Remarks.—The literature upon the subject of hydrocephalocele is very meagre, and Dr. Gross, the author of the term craniomeningocele, says but little about it in his work on surgery. As I found the case it was a hydrocephalocele, the tumor being composed of the scalp, the membranes of the brain, cephalo-spinal fluid and a portion of the brain; but after returning the latter within the skull, the remaining tumor became a craniomeningocele, and as such, I believe it to be the largest on record. The blood mixed with the serum in the sac came from the severed vessels of the scalp.

The final result corresponds with all the cases recorded; but believing the tumor, while in utero, to have been one of craniomeningocele, I think had it been so detected, the accouchement conducted accordingly, and operation followed as above described, that a more favorable ending might have ensued.

In the removal of the ligature, I am aware that there was danger of hemorrhage from the meningeal vessels, but not more so than in Jobert de Lamballe's favorable case in trephining and opening the meninges in exploring the brain.

Santa Barbara, Cal. A. B. Stuart, M.D.

Medical Confessions.

Ed. Med. and Surg. Reporter.

In the Reporter of December 11th, No. 24, we find an article entitled "An Excusable Mistake."

I feel much indebted to the author for his frankness of spirit—yes, a generous spirit; an open-hearted frankness—and the idea very naturally causes some of us to review some of our own mistakes, and say, "He that is without sin among you, let him first cast a stone."

In the more verdant days of my practice I, no doubt, would have said, why did not the doctor do thus, or otherwise, and know the difference between hemorrhage from a tooth and hæmoptysis? This would be but an expression of selfish human nature, which is far more ready to censure than to approve. But at this period I can say I do not know exactly what I should do, until placed in that particular position; as the spectator of a game may see points which the player does not, on account of his mind being loaded with other consequences. How we all love our successes and hate our failures! Hate them, even to the extent of trying to rid our minds of them, as being too unpleasant to think of. Yet, is he not wise and great who can look upon adversity and prosperity with equal candor and firmness? Are not some of the mistakes we make our very secrets of success?

Answering this in my own case, I can give a positive yes. Though my medical life has not been made up of mistakes, they have been sufficiently numerous to be plainly seen. As I entered practice, armed with graduation, I soon found that much of the good teaching of my professors had been very wrongly comprehended by me. After administering to a child a carefully proportioned dose of aconite, and finding that it was only by timely interference and the use of the proper antidotes that the child was saved from the effects of an overdose; after seeing like effects from doses of different drugs, given with the greatest mathematical accuracy; after seeing that I have used the obstetric forceps in cases where time and lard should, by all means, have been the remedies; and after meeting the disappointments in the administration of remedies, and finding the failure due to my own laziness and lack of care; I can truly say that these professional errors are among the greatest secrets of my success to-day.

Greatest? Yes, certainly, greatest! The adage "easy come, easy go," is not always true. A mistake in practice may come easy but it cannot go easy. It leaves a lasting picture and impression upon the mind. It will be a guiding star in times of darkness. Let who will censure us for relating to each other our professional mistakes. Open confessions are good for the soul, and certainly they will result in good to the general practitioner and likewise to his patients. Let us hear from others. J. F.

[We applaud the above as the expression of what all honest practitioners feel. The man who says that he never makes mistakes is a man not to be trusted. He either aims at deceiving others, or his gross ignorance deceives himself. What the writer says about the instructive character of mistakes is also most true. The thoughtful man learns more from them than from his successes. The latter may be only lucky hits; but of the former there is, alas! but one interpretation. Why may not the general profession, also, learn more from its failures than successes? So it could, were such properly reported. As we said last week, this journal maks a special bid for *unsuccessful* cases, for *failures*, for *errors*, for blunders, if you will. While every respect will be paid to the confidential characters of such statements, they will be utilized for the good of all.—Ed. Reporter.]

Sclerema—Result of Autopsy, Microscopic Examination, Etc.

Ed. Med. and Surg. Reporter:—

Sensational newsmongers gave the credulous public a surfeit of matter pertaining to this case during life, but it is our privilege to call the attention of the medical profession to actual facts gleaned from the friends of the deceased, and conclusions based upon the results of the autopsy.

The child was a son of Mr. and Mrs. Jacob H. Kinsely, of New Philadelphia, O. The child at birth was healthy and of normal size. The first appearance of disease was observed at two years of age, when the child had an attack of porrigo favosa, which readily yielded to appropriate treatment. A short time subsequent to this the scleremic condition first became apparent, commencing in the palms of the hands and soles of the feet, and extended from thence over the entire body. The palms of the hands, to the touch, resembled sole leather, and by the ignorant were supposed to be petrifying or turning to stone, and he soon was known under the soubriquet of "The Petrified Living Child."

When disease had extended over the entire body, there was general induration of the entire surface, it being very cold and of a glassy appearance. The knee, elbow, and second phalangeal joints became perfectly anchylosed, with contraction of limbs. The occipito frontalis muscle became fixed to the skull, and the orbicularis palpebrarum became immovable—compelling the child to sleep with its eyes open. The child took nourishment ordinarily well, its digestion seemingly good, and suffered but little apparent pain.

On Monday, Dec. 6, 1880, the child contracted a cold; on Friday grew worse, when a physician was called, and it died the Saturday following, at 5 o'clock, P.M., aged 3 years, 1 month and 2 days. The remains were placed in a vault, and on Tuesday following an autopsy was conducted, under the supervision of the following medical persons: Drs. J. T. McCane, J. Hill, G. H. Peck, T. J. Richards, —— Tinker, and Mrs. Dr. Anna Richards, of New Philadelphia, O., and Dr. J. T. Goucher, of North Lawrence, O.

The conclusion of the post-mortem revealed congestion of the lungs as the immediate cause

of death. Sclerema, or hardening of the skin and the loose connective subcutaneous tissue was general and extensive. Beneath the skin was found a dense layer of white-yellow fibrous tissue, 1⅛ inches in thickness, closely compact, and very dense in structure.

A microscopic examination of a portion of tissue removed from the left forearm by Professor J. N. Miner, of Medical Department of Wooster University, revealed the following:—

Hypertrophy of fatty tissue, subcutaneous fatty tissue. The layers of epithelium on the surface not above half as thick again as natural. The epithelium not the specific seat of disease. The fatty tissue consisting of closely packed cells, large and closely packed together in meshes of connective tissue, which seems to have crowded the papillæ out of existence.

The sclerema in this case was doubtless owing to a scrofulous diathesis existing in the child. The treatment was as varied as the number of medical men who were called to see the case. For the greater part, hot baths, friction, and electricity were the remedies relied upon.

J. T. Goucher, M.D.

North Lawrence, Ohio.

Unchangeable Character of Diabetic Urine.

Ed. Med. and Surg. Reporter:—

In your Medical and Surgical Reporter of Dec. 18, 1880, page 538, is a short article about diabetic urine remaining unchanged for several months.

During the latter part of last winter I had a case of diabetic urine which proved fatal. During his sickness I made many examinations of it for sugar; a day or two before his death I saved some in a 4 oz. vial, which I took to my office, and after giving it several tests for sugar, I set it away in an out of the way place out of doors, where it was exposed to the hot sun for some weeks. One day a person came to my office who suspected one of his family was afflicted with the disease, and the subject of the tests was freely explained. Thinking of this bottle and that perhaps I could show the test, I went and got it, and was very much surprised to find it so well preserved. There was no odor, but little sediment, and the test for sugar showed as well as the day it was procured.

In this case there had been no salicylic acid given, but he had been a very intemperate man for some years.

If the above is worthy of a place in your journal, you are welcome to it.

West Troy, N. Y. R. H. Sabin, M.D.

A Wonderful Surgeon.

Ed. Med. and Surg. Reporter:—

The following paragraph caught my eye lately, in a medical journal.—

An East Indian Surgeon, Ram Sundar Gose, is said to have performed lithotomy five hundred times, inaugurated charitable dispensaries in wild and remote districts, organized four hospitals, besides vaccinating one hundred and sixty-three thousand in two years.

It does not appear clearly whether the words "in two years" apply to the whole of his work, or to the vaccination only; but taking the latter supposition, a little calculation will show that the gentleman must have averaged five hours a day, vaccinating a little over forty four patients an hour, to have accomplished this feat. The remoteness of his residence enables one to express a doubt as to the accuracy of the statement, without the risk of suggesting a "vaccination match." If true, it certainly seems as if Mr. Ram Sundar Gose might claim the lofty position of champion vaccinator of the world.

Philadelphia, Dec. 10th, 1880. P.

News and Miscellany.

The Premiums Continued.

The premiums which we offered to old subscribers who, along with their own renewals, will send us the subscription price of a new subscriber, will, at the request of several correspondents, be continued until February 28th. These premiums are specified on page 523 of last volume (Dec. 11th, 1880), and need not be repeated here.

We avail ourselves of this opportunity to thank our numerous friends who have exerted themselves in our behalf, and have sent us already such agreeable additions to our lists.

New Plan of Gauging Physicians.

Some time ago we referred to a scheme called "The Physicians' Protective Register Company," started in this city (Reporter, Nov. 13th, p. 440). A writer in the *Daily Times*, December 31st., sends a letter to that journal, which we quote in full, for the benefit of the profession in this and other cities where such schemes are set on foot:—

"Your article in to day's *Times*, on 'Medical Wheat and Cockle,' as presented by the 'Physicians' Protective Register Company,' is apt to mislead the public as to the truth in the case. From my official position in the Philadelphia County Medical Society, I know that the matter is neither indorsed nor countenanced by the Society nor its prominent members. In common with many members of the County Society, who are also members of the State and American Medical Associations, I was neither called on nor did I answer the notice referred to, simply because the whole affair is an advertising scheme in the interest of its publishers. From a canvasser I learned that those gentlemen who declined to pay the three-dollar fee would have their names omitted, and upon suggesting that trouble might arise under such circumstances, he remarked that the "name" might go in, but the column of "place of graduation" and "date" would in such instances be left blank, thus directly classing educated gentlemen of long standing with quacks and imposters. Furthermore, the public care little about the matter, having confidence in their family physician, and respectable members of the profession take no interest in advertising dodges of any kind."

Removal of a Ring.

A correspondent in Middletown, New York, sends us the following:—

"I had a call about 4 o'clock one morning, from a stranger, who informed me that he had been traveling about all night after help, which he had thus far failed to obtain. He showed me a thick gold finger-ring on his penis. I was startled into an expression of curious surprise, which he did not satisfy, but requested me to remove it. On examination I found the ring was close to the pubis, and the organ outside excessively elongated and enlarged. The ring embraced the root like a string around the neck of a bag. I sent for a jeweler, and after ten minutes' work he sawed through the circlet, and we drew it apart with two pairs of tooth forceps. The patient quietly paid his bill, pocketed the ring, and took a dignified departure. I have heard of him since in good health."

Case of Hæmophilia.

The Chicago papers are interested in a case of hæmophilia. An account in the *Daily News* runs:—

"Willie Crawford, aged seventeen years, son of Willie Crawford, captain of a tugboat, has for seven years been sweating blood at times, and lately had severe attacks, which alarmed his parents. His infirmity comes on him usually after taking cold. Great black patches appear on his body, from which blood drops the size of a pin head exude. Blood flows from his mouth, nose, eyes, stomach, and even from the bladder and kidneys. No pain accompanies these discharges, but they make his blood thick and weaken him. Sudden fright or excitement will temporarily check the flow. He is mentally bright, and his father, mother, brother and sisters are strong and healthy."

Such cases are not extremely rare in the history of medicine.

Medical Matters in Spain.

A foreign exchange tells us that in each quarter of Madrid there is, by law established, a house where four to six beds are always held in readiness to receive any persons suffering from accidents or sudden illness, and whom it would be difficult to transport either to the hospital or to their homes. At each of these depots there are two or three doctors, according to the importance of the district, two nurses, a clerk, and two stretcher-bearers. Both day and night a medical man remains on duty at this post, and he has with him the necessary surgical instruments, bandages, medicaments, etc. This institution is in vogue in all the large towns of Spain. The medical attendants receive fair remuneration, and are appointed by public competition. These appointments supply practice to young doctors, and enable them to tide over the earlier and more difficult period of their careers. For a village of forty poor families and one hundred and thirty cottages and houses, the local authorities pay the medical man a yearly salary of $115, and the well-to do inhabitants contribute $385.

The Pennsylvania State Lunatic Asylum.

Many of his professional brethren will regret to learn that Dr. John Curwen has been removed from the position of Superintendent of the State Insane Asylum, at Harrisburg. The principal cause was his alleged and unwarranted assumption of authority, and his extravagance in the management of affairs. Dr. Curwen has held the position of Superintendent of the Harrisburg Hospital for the Insane nearly thirty years, and is widely known throughout the State, this being the oldest institution of the kind in Pennsylvania. His third term of ten years would expire early in January. His successor, Dr. J. C. Gerhart, has been first assistant of the hospital for eleven years, and is eminently qualified for the position by education and experience. He studied medicine with Dr. Atlee, of Lancaster, and has made the subject of insane hospitals a special study in this country and in Europe.

Personal.

—Dr. C. F. Ehrenfield, State Librarian, is lying seriously ill with pleurisy, at Harrisburg.

—Dr. A. A. McDonald has been elected physician-in-chief of the Department of the Insane of the Philadelphia Almshouse.

—Dr. J. A. Thacker, of Cincinnati, who is devoted to microscopy, received a pleasant Christmas gift, in the shape of an announcement of his election to the Royal Microscopical Society, of London. This honor was the more grateful that it was unsought and unexpected.

OBITUARY NOTICE.

—Dr. David P. Smith, professor in the Yale Medical School, and one of the best known physicians and surgeons in the Connecticut valley, died in Springfield, December 26th, in his fiftieth year.

QUERIES AND REPLIES.

Reprints and Short Monographs.

Dr. Oliver and others ask how they can obtain the reprints and short monographs noticed under "Notes on Current Literature." We reply that, as a rule, we give the authors' addresses, and that they should be written to personally for them. We, ourselves, usually receive but a single copy, which is filed.

Dr. L. G. A., of Ky.—You should address the Surgeon General U. S. A., Washington, D. C., to obtain the information you wish.

Dr. L. K., of Va.—The expression "sideration of the heart" has been used by some French writers to denote an abnormal cardiac action, which is the opposite of palpitation; in other words, a sudden stopping of the beat for a few seconds.

Scrutator desires any facts which seem to point to the development of cancer from constitutional or hereditary syphilis. If sent to the editor of this journal, they will be either published or forwarded.

MARRIAGE.

PETTINGILL—ALLISON.—On Wednesday evening, Dec. 22d, at the residence of the bride's parents, by the Rev. F. E. Bessey, Ed. L. Pettingill, M.D., and Ida Leonor, youngest daughter of Wm. H. Allison. All of Hancock, N. Y.

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

Trade supplied in Philadelphia by

1215-1267eow ROBERT SHOEMAKER & CO.

J. C. BAKER & CO'S. COD-LIVER OIL.

Absolute Purity and Freshness

Secured by Specifying our Brand.

Prepared on the **HALTEN ISLANDS, NORWAY**, with great care, from the finest selected livers of **NET-TAKEN COD FISH**, at a season of the year when they are in their highest condition.

PRIZE MEDAL—PARIS, 1878; BERLIN, 1880.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda, containing fifty per cent. Pure Oil, is a perfect and potent preparation.

☞ We employ Baker's Cod-liver Oil in preference to all others. The Pure Oil is palatable and digestible, and the Emulsion is well nigh delightful.

Drs. YANDELL & COWLING, Louisville.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

PNEUMONIA.

BY HIRAM CORSON, M.D.,

Of Conshohocken, Pa.

During the last several years nearly all the prominent men of Philadelphia who have died have been carried away in a few days, from a state of health, by pneumonia. Such were the press reports in the cases of General Meade, Judge Cadwallader, Bayard Taylor and many, many others of the eminent men; and it has astonished me that while pneumonia has been so fatal in the city, as all must confess that it has been, we should not, in any report of any medical society, have an account of the progress and treatment of a single one of the cases, or an article on the approved treatment of the dis ease.

I have repeatedly inquired in relation to the treatment pursued by physicians in Philadelphia, but have failed to discover more than this: "That they never bleed, for fear of so weakening the patient that he will not be able to stand the exhaustion of the last stage;" and on inquiring what is the last stage? I am told, "The stage of purulent infiltration." Second, that the frequency of the pulse is reduced by verat. viride, the heat of the body by large doses of quinine, and the strength of the patient maintained by the early, continuous, and I may say, copious use of beef tea, milk punch, brandy or whisky, and whatever else of the most nourishing food can be used; all these things done in the hope that the patient will be able to bear up until all the stages have been gone through.

Now what are these stages? In other words, what is this disease? I have read very carefully, over and over again, what Ziemssen and his German co-laborers say about it, and I find that inflammations of the lung begin in the same way, run the same course, and have terminations alike, wherever they occur. The works on practice, during the last fifty years, all give the same account of its invasion, progress and termination. First stage, congestion, by some better termed inflammatory engorgement. It is quite easy to call it inflammatory engorgement, but what is the condition of the lung now? Juergensen says: "the lungs in that stage are of a dark-red color, heavy, firm, and retain the depression caused by the pressure of the finger; showing that they contain little or no air, but fluid. On section, the substance is found to be dense, the result of swelling of the tissue and infiltration with a bloody, serous fluid. Next comes the second stage, hepatization, marked by a very adhesive, viscous, reddish-brown, secreted fluid." This second stage is the one which is very generally present when the physician is first called, marked by the viscous, bloody and rust-colored expectoration. Juergensen continues: "The lung is now, internally and externally, of a dark, brownish-red color, solid, but easily torn; no longer crepitates. On being cut, usually exudes—only on pressure—a brownish-red, opaque, bloody, serous fluid. This condition, known as red hepatization, soon changes into the third stage proper, that of purulent infiltration. The cut surface is now of a straw-yellow color, and from it exudes, in large quantity, a very viscid, purulent fluid, of a faint odor." It is the exhaustion of this purulent stage that the persons who follow what they call

the supporting plan, and who oppose taking blood from the arm, dread. They believe that the disease must go through its course—its three stages, and therefore they do nothing to arrest its progress, but are very busy feeding, and watching, and waiting; they pay many visits, are wonderfully strict with the nurse, see to it that she has the whole chest enveloped by poultices, and changed for fresh ones, every few hours; themselves attend to the making of the milk punch and whisky toddy, from the very best whisky, gotten at their favorite druggists'. They do nothing to prevent the congestion—which, of course, occupied but a small part of the lung for the first few hours—from being extended to other portions of it; or if they have not seen the case until the inflammatory engorgement has already occupied a great part or all of the lung, do nothing to arrest its passage into the third stage, which I will call the stage of suppuration; a stage from which they can rarely rescue their patient.

Now, all their treatment seems to me to be wrong—wrong in principle and wrong in practice. Their principle is that, the disease being one which, like smallpox, will run a prescribed course, always the same in point of time, differing only in degrees of mildness or severity, it is their duty not to attempt to arrest its course, but to keep up the strength, so as to bear the suppuration going on in the whole of one lung. We who follow the treatment used by physicians many years ago, to allay acute inflammation wherever situated, utterly scoff at the idea that we cannot arrest the course of pneumonia. We believe it one of the most curable of our diseases, and we say this from our own experience of it. Even Ziemssen says of croupous pneumonia, now so greatly dreaded by many: "When it occurs in a hitherto vigorous individual, not weakened by age, excess in eating or drinking, or other diseases, *it is the least fatal of acute affections.*" Every reader of your journal will admit that pneumonia has come to be a greatly dreaded disease—a very fatal one under the strength-preserving treatment, by quinine, whisky, aconite or veratria, milk punch, beef tea, hot poultices, etc.

I divide all practitioners who treat this disease into two classes: those already described, and those who practice by cupping, cool baths, or cold applied in other ways, to reduce heat, without caring, for the first few days, whether the patient takes food or not, the object of the treatment being to allay an inflammation of the lung, which, if unallayed, will be almost certain to destroy life. We of the latter class—but it is hardly fair to drag others into the support of my views, so I will not use *we* any more, and you will, therefore, allow me to say I believe that the earliest congestion of the lung goes on for a short time without evidence to the patient that anything is wrong with him, but in a few hours this irritation, which invited the flow of the blood to the part, and which has filled the capillaries of the lung tissue with an excess of blood, and which, by their engorgement, are obliterating the cavities of the air-cells, produces a chill on the surface of the body. Some physicians—not a few—there are, who regard the chill as the cause of the congestion. They say, "He took a chill, and it fell on his lung; produced a pneumonia." I have often known physicians, when called to a patient who had had a chill, say to him, on being asked what he thought the affection was, "well, it is hard to say yet; we will see after awhile where the chill will strike;" impressing the patient with the belief that the chill was an evil thing which was running all over his body, to see where most fatally to strike him. I do not believe there ever yet was a chill which was not preceded by some local disease already under way in the system.

I regard pneumonia as simply an inflammation of the lung tissue, and I don't worry myself to distinguish between catarrhal pneumonia and croupous pneumonia, for it makes no difference, so far as treatment is concerned, which it is; and because, too, that neither myself nor any one else can tell which it is during that time when treatment is so indispensable. Even Juergensen says, "It will be found very difficult, and perhaps impossible, to draw the distinction between a case of catarrhal and one of croupous pneumonia, if one does not see the case until consolidation is complete." When is consolidation complete? Why, in the first stage. He says of them then, in the first stage, "they are of a dark red color, heavy, firm, and contain little or no air."

We have thus shown how this disease progresses; now, what is it? The same author says: "Croupous pneumonia, anatomically considered, is an acute inflammation of the alveoli and bronchioles, in which a fibrinous exudation is poured out on the free surface of the mucous membrane and there coagulates." I am almost ashamed to have taken up so much of your space with a description of this disease, which, after all, is simply *an inflammation of the substance of the lung.* Talk of the alveoli and the bronchioles!! as if they were something separate from the lung. Why they are really, with the blood vessels and

nerves, the whole tissue, formerly spoken of as the "parenchyma" of the lung.

Having now come face to face with an acute inflammatory affection of the lung, our business is to arrest it. If we see it and recognize it in the stage of congestion, when it is hourly spreading further and further through the lung, we can arrest it at once. It shall not pass into the stage of red hepatization. He has had a chill; has some pain, perhaps; coughs somewhat, and there are traces of blood, indeed, bloody serum and even blood and some traces of rusty sputa; the blood is rapidly distending the small blood vessels of the lung; the heart is beating rapidly; the man is hot, oppressed, restless, and with a sense of great weakness. What, now, shall we do? Will quinine, or aconite, or verat. viride, or whiskey punch, or hot poultices over the chest, or all of them together, arrest the flow of blood which, invited by the irritation of the lung, is rapidly filling up and distending, almost to bursting, the tens of thousands of capillaries? No! not one of those means will be of any avail: and yet intelligent men will stand by the bedside of an eminent man, and rely on those means, while their patient becomes more and more oppressed, choked and suffocated, by the lung being filled with blood, to the exclusion of every particle of air. But the physician is not idle, nor listless; he is anxious, and he has called another to his aid, and the two have called a third, and now the treatment is urged with greater force; the medicine and the food are both increased, while the theory of its being a constitutional disease—a blood disease—is canvassed, and all agree that his evident weakness is proof of the depressing nature of the poison with which the blood is filled; and now, that the poor man is gasping for breath, and his strength is failing for want of air in his lungs, the syringe, filled with "the most nourishing substances known to the profession," is brought into use, but all in vain. "It would have terminated well if we could have kept up his strength until the disease had run its course."

I do not like to write thus; but I have been agonized to see our best men, and men, and women and children of all classes, sacrificed to treatment that has nothing to sanction it, neither reason, nor experience, nor common sense, nor the well established action of any of the means on which they rely. They have had much talk about the change which half a century has wrought in the human system, deteriorating it, weakening it, so that the loss of a few ounces of blood during the progress of any disease would be hazardous to life; and yet not one of the trio, perhaps, had ever seen the effect of that measure in the treatment of a disease.

You are anxious, by this time, to know how I regard this disease and how I would treat a case. To me, it is simply an inflammation, and I would use rapidly, as early as possible, the means which, in a practice of half a century, I have found safe and most efficient in allaying inflammation. Well, here is my patient; he had a chill hours ago; he has some pain in his side, some cough, he feels very weak, his face is flushed, he is hot and thirsty, his pulse is over a hundred, the thermometer rises to 103°, he breathes scarcely at all through most of one lung; there is a little blood and viscous fluid, slightly rust colored, in the basin by the bedside; he knows how he got sick; he "was down in the iron ore shaft all yesterday, at work; came up in the evening to come home, and being in a perspiration, soon, in facing the wind, cooled off too suddenly." I propose to bleed him; he objects, on account of his great weakness. I tie up his arm, bleed him twenty ounces, or perhaps he feels faint by the loss of less than that; he expresses himself as being relieved somewhat of his oppression; he can lie more comfortably, he feels relieved of the fullness in the chest, but still he has a little pain in the side, or in the breast just above the nipple. I order him one-quarter gr. sulph. morph., direct that a towel wrung out of cold water, ice-water, if convenient, be applied over the affected part, to be changed frequently—or substituted by a bladder of ice and water. Then directing a mixture which contains some spirits of nitre, with about the 32d of a grain of sulph. morph. to a teaspoonful every two or three hours, I leave him, with an express direction not to worry him by any offer of food. Next day, or even the same day, perhaps, if I find that he is not entirely relieved of the pain, and is still expectorating viscid sputa, I bleed him again freely, and if need be, cup him, and after that he is generally safe. Some one will say—that may do very well for your strong iron-ore diggers, but it would prove fatal to our delicate patients. Perhaps so, but in my experience I have found that the weak and frail need to have the same means used to allay a toothache or a sciatica, a pleurisy or a rheumatism, as the robust. They bear the remedies to cure an ague as well, and need them as greatly, as the strongest. I have often bled the infant strangling with croup, with immediate relief; weak women with pleurisy or pneumonia, old men and aged, very aged women, to relieve affections of the brain, or avert a paralysis.

I believe there has not been any change in the human system in this climate which has made it more hazardous to take blood from the sick than it was forty years ago. But I must close, and ask of you to give me place for another number, in which I may illustrate more fully my views and practice.

(To be Continued.)

DIGESTIVE AGENTS IN INFLAMMATORY RHEUMATISM.

BY S. V. SWERINGEN, M.D.,
Of Fort Wayne, Ind.

It is not my purpose to attempt an exhaustive treatise upon the history, pathology, etiology and therapeutics of acute articular rheumatism. My aim is, rather, to induce the profession to make a trial of the remedy I propose to introduce, inasmuch as my own data are insufficient to warrant any positive conclusions as to the confidence it should merit in the treatment of this disease, and as a considerable period of time may elapse before another case of it will occur in my practice.

The therapeutics of rheumatic fever is, in my opinion, as unsatisfactory as its etiology and pathology; a fact which seems to justify the practitioner in resorting to experiment in its treatment. This was the light in which I considered the subject when called recently to treat a case of the disease under consideration.

Heretofore, in the management of this malady, I have pursued the plan of treatment generally recommended by our authorities: the administration of alkalies, salicylic acid, salines, quinine, tincture of iron, colchicum, lemon-juice, opium, salicin, the application of blisters, leeches, wrapping the joints in cotton, etc., etc.

The results in my hands, of this routine of treatment, have been so universally unsuccessful, that I finally directed my attention only to the relief of pain and the protection of the heart, and waited patiently for the expiration of the "six weeks" (or eight or ten, as the case may have been), for convalescence to become established.

In a typical case, however, which I am about to relate, after three days of treatment by the old plan, I decided to forsake it and employ some new agent which, to the best of my knowledge, had never been prescribed.

On the first of the present month (Dec., 1880), I was called to see George Humphrey, aged 15 years. I found him bathed in an acid perspiration, and screaming with pain, which migrated from ankle to ankle, knee to knee, wrist to wrist, elbow to elbow, and from his right hip to his right shoulder. Temperature 104° F., tongue covered with a peculiar pasty, creamy coat, pulse beating at the rate of 140, rather soft and compressible. Urine somewhat scant in quantity, highly colored and acid in its reaction. The slightest touch upon the radial artery caused him pain, and it was with great difficulty that he could be moved at all. In short, it was a characteristic case of the complaint in question, the cause of which he attributed to sleeping in a damp bed away from home.

I immediately directed the following treatment:—

℞. Acid salicyl.,
Quin. sulph., āā ℥ ss
Opii pulv., grs. vj
Morph. sulph., gr. j. M.
Ft. capsulæ No. vj, div. et.
Sig.—One capsule every four hours.

℞. Potass. acet., ℥ iij
Sprts. æth. nit., f. ℥ j
Tr. aconit. rad., gtt. xv
Syr. ipecac., f. ℥ ij
Liq. am. citrat., q.s. ad f. ℥ iv. M.
Ft. sol., et.
Sig.—A tablespoonful two hours after each capsule.

℞. Sodæ et potass. tart., ℥ ij.
Sig.—Add to a glass of water and give one-third of the solution every two hours, until it operates freely on the bowels.

Pursuing this treatment for a period of seventy-two hours, and noticing no improvement in his condition, other than that which might be naturally expected from the effect of the opiates, which, only to a moderate degree, however, mitigated the pain, I began to cast about, mentally, for some other remedy.

It was necessary, of course, to frame some theory as a basis for the selection of the new agent, and jumping at the conclusion that the predisposing cause of the malady was some unknown error in digestion, either gastric or intestinal, or both, the idea that lactopeptine or ingluvin might be of some benefit, at once suggested itself. I decided to give both, and accordingly left the following prescriptions:—

℞. Lactopeptine,
Ingluvin, āā ℥ ss
Opii pulv., grs. viij
Morph. sulph., gr. j. M.
Ft. capsulæ No. vj, et.
Sig.—One capsule every four hours.

Not wishing to discard entirely the usual time-honored treatment, sanctioned by so many able authors, I alternated each dose of the foregoing

prescription with a tablespoonful of the following :—

℞. Potass. iodid., ℥j
Potass. bicarb., ℥iij
Aquæ destil., f.℥iij
Tr. colch. sem., f.℥ij
Tr. gent. co., f.℥iij
Syr. simp., q.s. ad f.℥iv. M.
Ft. sol., et.

Sig.—A tablespoonful two hours after each capsule.

Upon my next visit, which was made after the expiration of twenty-four hours, I was very much surprised, indeed, to notice such a well-marked general improvement in the condition of my patient. His parents were likewise happily astonished, for I had prepared them to expect a six weeks' siege of the attack. The pain, swelling and temperature had decidedly subsided, and he could now move a number of muscles with comparative ease.

Fearing that his apparent convalescence was a mere respite, but of short duration, and that the enemy would ere long make a fresh and more vigorous attack, I directed the prescriptions to be renewed and taken as before.

Upon my next visit, twenty-four hours subsequent, I discovered that my patient had arisen from his bed, dressed himself, and walked down stairs into the sitting room, where I found him feeling quite comfortable ; convalescence having rapidly progressed unchecked. Of course, all these efforts upon his part were not made without the assistance of his attendants. From this period up to the present his condition has been one of continued improvement, and he has now apparently regained his former health.

Now, if it were not for the fact that the latter prescription figured prominently and faithfully in the treatment of three cases which I had under care at one and the same time, in the spring of 1878 (and which pursued the "even tenor of their way" for six, eight, and nine weeks, quite unimpressed with my best efforts at medication), I should be inclined to attribute to it the success achieved in the case just related. I failed to detect any particular good that it accomplished in the cases referred to, and hence feel justified in the present case in giving the credit to the lactopeptine, or ingluvin, or both.

But this is simply an individual case in my own individual experience. It must stand the test of collective experience in collective cases, and for this purpose I present it to the profession.

197 *West Wayne Street, Dec.* 15, 1880.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

A CLINICAL LECTURE DELIVERED APRIL 21st, 1880, BY WILLIAM GOODELL, M.D.,

Professor of Clinical Gynæcology in the University of Pennsylvania.

REPORTED BY WM. H. MORRISON, M.D.

Laceration of the Cervix Uteri.

Gentlemen :—The first patient I shall show you is a woman who comes to be operated on for a stellate laceration of the cervix. By a stellate laceration, we mean one in which there has not been one clean tear, but in which there have been several tears. I have here the letter which she brings from her attending physician. He says that she has complained of uterine troubles since the birth of her first child, six years ago. Shortly after her confinement, diarrhœa set in and continued a year and a half, until she was seven months gone in her second pregnancy. Her last labor was the hardest of the three. After this the diarrhœa returned and has since been controlled with difficulty ; returning on any change in the weather and after any extra exertion. She came under the notice of this gentleman when her first child was seventeen days old. During a portion of the time she has been wearing, with some advantage, a ring pessary. Treatment, local and general, has removed all the troubles except those due to the laceration, for which she comes to-day to be operated on. Her physician suggests that, owing to the irritability of the bowels, it would be better to relieve them by the use of an enema instead of by laxatives by the mouth.

Now let me point out the significance of some of these facts. The first labor took place six years ago. The laceration probably occurred at that time. When the cervix is torn in this way, it turns back on itself, just as a piece of celery will curl when it is split. We thus have the mucous lining of the cervix exposed to friction. At every motion she makes, as in walking, the delicate epithelium, which is neither tessellated nor conoidal, but rather spheroidal, is rubbed off. Then, in intercourse with her husband, the male organ impinges upon this raw surface and causes more irritation.

Why was she benefited by the ring pessary? When there is laceration of the cervix, the womb does not undergo involution properly, and so is heavier than normal. The ring pessary, by dilating the vagina, kept the womb up and took the tension off the ligaments It also, by dilating the vagina, helped to prevent friction.

I shall now have the patient brought in. What is the treatment in the acute form? The difficulty, gentlemen, is in recognizing the acute form. Immediately after labor, the cervix is so soft and limpid, that it is often impossible for even a skilled finger to decide whether or not there is a laceration. Even when it is discovered, I doubt the propriety of passing sutures at this time. I do not believe that it is right to do so unless there is considerable hemorrhage. If

there was much bleeding, I should introduce sutures to stop it; but under other circumstances I should prefer to trust to nature and cleanliness. I believe that in the majority of cases these lacerations will heal spontaneously, if the parts are kept clean. Injections of a two per cent. solution of carbolic acid should be made once or twice daily. It is asking too much of nature to heal a laceration which is all the time lying in a pool of stinking lochia.

This is the pessary that she has been wearing. It is a ring pessary, I think introduced by Dr. Peaslee and made by a firm by the name of Otto, in New York. It consists of strips of whalebone, covered with rubber.

Now, gentlemen, you can see what is very often mistaken for an ulceration, and in one sense it is an ulceration. This is a stellate laceration. There are four different points of laceration, making it a difficult case to operate on. This is what a great many physicians call an ulceration, and try to cure by the treatment for an ulceration. The treatment usually consists in the employment of the solid caustic. This causes cicatricial tissue, which contracting, involves and presses upon the delicate nerve filaments, so that the woman's last end is worse than the first.

The only thing to be done in this case is to restore this denuded mucous membrane to its normal position. For the sake of illustration, let me call your attention to an example of a similar condition. You have seen persons who, as the result of some accident, say a burn, have had the eyelid drawn downward, and there is produced an ectropion. The delicate conjunctiva being exposed to the action of the air, soon becomes irritated, inflamed, and the seat of a discharge. The same condition is present in laceration of the cervix. We have ectropion of the mucous membrane; that is the long and short of it.

Putting in the duck bill speculum and catching the cervix with a tenaculum, I next determine the position of the womb and of the os. It makes the operation much easier when we can draw the womb down, as we do here. The womb is in a state of dextro-lateral flexion. The first thing I shall do will be to unite two of these slits, by taking out a wedge-shaped piece. One difficulty we meet with is due to the friability of the tissue, making it difficult to hold on with the tenaculum.

This operation is one of the most successful in gynæcology. I prefer not to do this operation before the class, for two reasons. First, because the light in this room is so poor, and secondly, because this is an operation requiring slowness of execution, and the tendency here is to hurry too much, particularly as you cannot see much of the operation.

I am going to turn the cervix over to the left side, as I find it more convenient to do so. I remove a wedge-shaped piece of cicatricial tissue here, as it prevents the bringing of the two raw surfaces together. Dr. Emmet was the first to point out the significance of this procedure. I used to be very careful not to get the os too small, but lately I have not been so particular, for I know that if I make it too small, I can easily make it larger by sudden dilatation; but if it is too large I cannot make it smaller, except by a second operation.

These lacerations are exceedingly common sources of trouble. So common, that I operated last week once, and shall operate in the course of the next ten days, including this case, four times. I have been thinking lately a good deal as to the reason why this is so common. I think there are two reasons for it. These so-called improvements in midwifery are, I think, in many cases, disadvantages.

The first reason is, the tendency to rupture the bag of waters too early, and thus remove the soft wedge so useful in the dilatation of the os. After the labor has progressed to a certain extent, it is, no doubt, well to rupture the membranes, but the temptation with the busy practitioner is to rupture them too soon.

The second is the too frequent application of the forceps. They are employed entirely too commonly by men who should not do so; but here again we have the same temptation to hurry. I venture to say that in six cases of forceps application, four of them will be for the sake of the physician. I may be making too strong an assertion, but that is what I think, and I will stick to it.

I find in almost all cases of complete rupture of the peritoneum, that the trouble has been caused by the use of the forceps, and in nearly all of laceration of the cervix, I find that the forceps has been used. The forceps is a noble instrument, and the man who invented it deserves the gratitude of the community, yet at the same time, there is such a thing as an abuse of the instrument.

I have now denuded these surfaces and am ready to pass the wires. I see here a couple of points that need a little more trimming. The greater care you take, the more successful you will be. I have only had one complete failure with this operation. It was in a strong, healthy woman, who was operated on before you, and the only thing to which I could attribute the failure was the hurry on my part. I have had partial failures, but that was the only complete failure I have had.

I have passed a double thread through the needle and tied it; I will fasten the wire to the thread and thus carry it through. I pass the wire in this way for fear that it might tear the tissues if I carried it through in the eye of the needle. I want you to watch Dr. Baer as he cuts this wire. Ninety physicians out of a hundred, that is my favorite illustration, would cut with the point of the scissors; but you see the Dr. cuts with the heel. That is the proper way.

I do not want to intimidate you in regard to the use of the forceps. I say to you, to put them on whenever you feel that there is a necessity for them; whenever you think that the woman requires them. I have told a story here before, but as it bears upon this point I will repeat it. I had a friend, poor fellow, he is dead now, who had a large practice among the poor, but never succeeded in getting into practice among the affluent. Just to show you how noble he was; he had a patient, and probably the only one from whom he expected a fee of fifty dollars for attending her during her confinement. When the mes-

senger came for him to attend this lady, he was at the bedside of a poor woman, from whom he would receive but a small fee. He sent word that he could not leave this woman. They sent a second time, saying that if he did not come immediately he would have to give the case up; but he stayed by the poor woman and lost his rich patient. Well, he used to apply the forceps quite frequently, and when we used to meet, he would tell me how many forceps cases he had had. One day as I was walking on one side of the street, he passed upon the other, and putting his hand to his mouth, called to me "forceps case last night." I asked him what was the reason. He answered "reed birds for supper." He afterwards explained to me, that he had invited some friends to take supper with him, and as he was in a hurry to get home, put the forceps on, to expedite matters.

Now, in the majority of cases, it is "reed birds for supper" that causes the physician to apply the forceps. This is wrong. When you get out into practice you will not have the coolness and experience to apply the forceps. I have seen physicians do things when they were excited over a case that they have been sorry for afterward. A French physician has written an essay on the "Delirium of Operators." A physician gets into a rough case, he loses his presence of mind and does that which he should not. For instance, the physician has been at the bedside of a patient for many hours; he is tired out. He puts the forceps on and commences to pull straight ahead, without giving the parts time to dilate. The damage done is not due to the forceps, nor to the pulling, but to the pulling too quickly, and then, when the head gets to the perineum, not waiting for it to bulge, but turning the head right out.

I have now turned the cervix to the left side, as I find it more convenient to do so, the cervix being small and the laceration stellate. I am now ready to tighten these wires; but here is another secret of success. I do not tighten them up right away, but as I am about to slip down the shot on each one, I open the wound with these spring forceps and inject some carbolized water. The main object in doing this is to remove any little clots of blood. The carbolic acid also destroys any germs which may be present, and thus prevents septicæmia.

What is the after treatment? I shall have her water drawn for four days, because if she gets up to pass it there is danger of the stitches tearing out; and if she passes it in a bed-pan, lying upon her back, there is danger of some of the urine running back into the vagina and getting into the wound. Sometimes I think I am too particular in regard to this point, but I have never yet had the courage to omit it. Six months ago they had a fire at Bellevue Hospital. My friend, Dr. Lusk, had that morning operated on a woman for laceration of the cervix. The fire broke out very suddenly, and the patients had to scramble for their lives. This woman went down three or four flights of stairs into the court yard. I believe it was snowing at the time. When the Doctor came to examine the stitches, he found every one in its place. As the womb is such a movable organ, I am disposed to think that perhaps it would be right to allow the patient to get up to pass her water, but I have never yet tried it. I told you, when I operated on the last case, that I should try this plan, but when I got up to the ward my courage failed me, and I directed her water to be drawn as usual. I am glad I did not try it in that case, for that was the one in which the operation failed, and if I had allowed her to get up I should have attributed the failure to that.

We will give her just enough opium to keep her bowels bound. That will be one grain of the aqueous extract of opium, by the rectum, every night. I always slip a suppository in immediately after the operation. There is very little pain following this operation. The woman usually suffers no more than at an ordinary monthly.

I now show you the result, and you see that this ulceration has entirely disappeared, and that the cervix is turned a little to one side.

I prefer the use of shot to twisting the wire, and I really think that there is some advantage in their use The shot act as little adjusters, and prevent any eversion of the lips of the wound. Dr. Emmet always twists the wire.

I shall remove the sticks on Thursday or Friday of next week. I used to remove them a week after the operation, but I now leave them eight or nine days.

The Diagnosis of Ovarian Tumors.

The next case, gentlemen, that I shall show you is ovarian tumor, but I, of course, do not intend to operate before you. I will tell you why. Many of you are engaged in dissecting, and some of you have just come from the fever wards of Blockley. You come laden with the germs of disease, such germs as will attack so vulnerable a membrane as the peritoneum.

The operation of ovariotomy is one that has taken great strides since the introduction of antiseptic surgery. I wish to-day to impress upon your minds some points in regard to the diagnosis of this disease. We are never positively certain that a cyst is ovarian, but ordinarily we should not make a mistake as to the presence of a cyst.

Let me read you the history of this case. She is a married lady, forty-eight years old. She has been married twenty-six years, and has had eleven children. The youngest is seven years old. Her catamenia ceased just about the time that she noticed the existence of a tumor, which was about Christmas, 1877. It rapidly increased in size until February 22d, 1878, when it was tapped. Just here let me say in regard to tapping, that it is a golden rule never to tap a woman until the interference with her breathing and circulation, from the pressure of the tumor, become so great that she is unable to bear it. This is a good rule, because when you once begin to tap you must keep on, and the intervals have to be shortened. This woman was tapped the second time three weeks after the first. She was tapped again in three weeks. Then every two weeks, and now she has to be tapped every week. She has been tapped, in all, thirty times. Last Friday she was tapped by Dr. Ashhurst, who then sent her to me. I have gone over her

case carefully, and as she will have to be tapped again in a few days, I have decided to remove the tumor on Friday.

Let me now call attention to certain points by which you may distinguish fluid in the abdominal cavity from fluid in a cyst. Some of our best men have made mistakes in the diagnosis of these tumors. There is not an ovariotomist who has not made a mistake. Not long ago an eminent English physician had a case which he had diagnosed as an ovarian tumor, and had appointed the day for operation. On the appointed day he invited a friend of mine to see the woman. The audience had assembled to see the operation. My friend went with him and saw the woman before she was taken into the operating room, and the moment he saw her face he thought it impossible that she could have so serious a disease. He made a vaginal examination, and found that it was a case of pregnancy, with dropsy of the amnion, the os widely dilated, and the child about being born. My friend suggested to the gentleman that he should make an examination. This he did, but pushing his finger in rather rudely, he ruptured the membranes; there was a gush of fluid, and in a short time the child, which in these cases is small, followed. I asked what the operator said about it. My friend said he never alluded to it afterwards. I asked what explanation he made to the audience. He went in and remarked that "there was an east wind blowing to-day, and as the patient was not feeling very well, the operation would be postponed."

Two weeks ago I had a case at the Preston Retreat. The woman said that she was pregnant. I made a careful external examination, and felt certain that it was an ovarian cyst, but a vaginal examination showed it to be a case of dropsy of the amnion.

John Hunter, a most excellent surgeon, tapped a woman for ovarian dropsy; the woman was taken in labor, and the child was born with the mark of the trocar in its shoulder.

The late Washington Atlee, who had performed more operations for the removal of ovarian tumors than any one else in this country, was in the country performing an operation. While at this place a woman came sixty miles to consult him in regard to an enlargement of the abdomen. He diagnosed it as an ovarian tumor, and appointed the day for operation. The woman was taken with labor pains on her way home, and her child was born in the depot that night.

We must always exclude pregnancy. This woman has not seen her monthlies for two years, and she has been tapped thirty times, so we can here easily exclude pregnancy.

Is this fluid in the peritoneal cavity or in a cyst? If it were in the abdomen, free to move, we should expect it to gravitate to the back of the cavity and float the intestines up. We should then have dullness in the flanks, and resonance in front. If it were in a cyst we should look for resonance in each flank over the colon. I will percuss this and see what the effect will be. In the upper part of the abdomen there is resonance, but this is due to the fact that the sack is not distended. A little lower down we have complete flatness. I do not get good resonance in the left flank, but in the right the resonance is marked. There is a source of error here, gentlemen, for we may have with peritoneal dropsy, adhesions of the colon to the abdominal walls; or, again, the effusion may be so large, or the intestines be so bound down by adhesions, that they cannot reach the surface of the liquid, and thus we will have dullness in front. In dropsy of the peritoneum there is flattening of the abdomen, while in ovarian cyst there is a prominence in front. In dropsy of the peritoneum, when we turn the patient over, the fluid gravitates to the dependent part. Looking at the history of the woman, we find that her health had not been failing for some time before she noticed the swelling, as it would have done if this were an effusion into the abdomen, for the causes that give rise to peritoneal dropsy are slow in their action.

I want you to look at this woman's face. See what wear and tear these tumors make. Her face is thin and wasted, and she has dark rings around her eyes. This is due to blood loss, or rather to loss of albumen, through this liquid. Last Friday five gallons of fluid were removed. This must have contained a great deal of albumen. We also have discolorations of the skin, as in pregnancy. There has also been change of color in the hands, and the skin is harsh and dry.

The fact that she has lost her monthlies might lead us to think that both ovaries were diseased. If she were younger, say forty years old, I should think that this was the case; but she is forty-eight years old, and it is time for the menses to cease.

I should like to have some of the fluid from this cyst, that I might examine it under the microscope. There is an ovarian cell, a peculiar cell found in the fluid of an ovarian cyst. It is not found exclusively there. It has been found in small numbers in pleural effusions; but if these cells are found in large amount in a fluid taken from the abdomen, you may rest assured that the fluid comes from an ovarian cyst. I have never known it to fail. I have a case which I had diagnosed as an ovarian cyst, and on which I intended to operate this week. I removed some of the fluid, and from an examination of it thought that it was ovarian. I sent some of it to Dr. Formad, to be examined microscopically, but he could find none of the ovarian cells. I feel certain now that it is not a case of ovarian cyst. It is probably a case of cyst of the broad ligament. So this may be a cyst of the broad ligament, but, anyhow, the operation is the same, and as I feel certain that this is a cyst, I shall not aspirate this tumor again.

When I operate, I shall make an exploratory incision at first, so as to be sure that I have made no mistake. I have thus far escaped any mistake in diagnosis. Her bowels will be moved on Thursday morning. Thursday night she will receive a grain of the aqueous extract of opium. Friday morning she will receive ten grains of quinia, and one grain of aq. extract of opium. She will have a light breakfast and nothing after, and at twelve o'clock I shall operate. Then, for the next forty-eight hours she will receive very

little food, perhaps, a little brandy and water, or a tablespoonful of milk and lime-water every two or three hours. I do this for several reasons; first, to prevent the intestines from having anything to work on; secondly, to prevent nausea from the ether; and thirdly, because the most successful operator, Dr. Diaz, of Edinburgh, keeps the women starved after the operation. He has had the astonishing record of seventy operations without one fatal case.

Last year I had eight cases, with one death, but that was due to no fault of mine. It was a case which had been tapped by a physician and inflammation of the sack set in. The woman had been expected to die before I saw her. When I was called to the case her pulse was 140 and the temperature 103°. She had marked septicæmia. I talked the case over with the attending physician. I said that for the sake of my statistics I did not care to operate, but I thought it was my duty to operate for the sake of the woman. I laid the matter plainly before her, and told her that she might die on the operating table. She was willing to have the operation performed, and said that she knew she had to die, but she would rather die without the tumor. I operated and found pus in the abdominal cavity and adhesion everywhere, from the severe inflammation. When I got through, I did not expect her to live more than a few hours. We gave her hypodermic injections of ether, and she rallied wonderfully, and for two days did very well. Then septicæmia set in, and she died on the fifth or sixth day after the operation.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

REPORT, IN BRIEF, OF THE AURAL DEPARTMENT.

Reported for the Medical and Surgical Reporter.

For the year ending October 1st, 1880, the whole number of cases of disease of the ear treated at the Aural Department of the Jefferson Medical College Hospital were 1701, out of which number 208 were first consultations. At each first visit a full history is taken, and daily notes are added, so that each case can be referred to and utilized in contributing to aural surgery and reporting otological novelties, testing various forms of treatment, arranging statistics, etc. In all, 49 operations were performed, such as those for traumatisms, the removal of tumors (fibroid, polypoid, sebaceous, etc.), paracentesis of the membrana-tympani (for acute and subacute otitis media), tenotomy of the tensor tympani, perforation of the mastoid process (for abscess), Wilde's post-aural incision (for periostitis), incision for supra- and post-auricular subcutaneous inflammation, removal of foreign bodies from the tympanum and external auditory meatus, etc.

The greatest number of visits were made during the winter months, when acute and subacute ear diseases (principally catarrhal) are so prevalent.

The majority of the whole number of cases treated were of middle-ear (tympanal) disease, and were of the non-purulent form, although there was a large percentage of the chronic purulent variety following scarlatina, measles and dentition, with a few due to syphilis, trauma, diphtheria, typhoid fever and sunstroke.

Of diseases of the internal ear there were, as usual, but few cases, these mostly owing to syphilis, cranial injury, acute, chronic and cerebro-spinal meningitis, typhoid fever, tubercle, concussion, etc. Diseases of the external ear alone, with the exception of eczema of the auricle and meatus, were rare, being, as a rule, symptomatic of existing middle-ear inflammations. Most of the cases of eczema of the external auditory canal were induced by the use of instruments of various kinds, in the hands of patients, for the removal of cerumen, or by the free use of the popular remedy, "old white Castile soap-suds."

Tinnitus aurium, the most annoying of aural symptoms, was noted in 161 of the 208 new cases, and the forms as described by individual patients varied, as did their occupations or walks in life. Noises accompanying external ear diseases were likened to the "singing of the tea-kettle, the roar of the surf, escaping steam," etc. With acute non-purulent middle ear disease, to "buzzing, roar of the surf, escaping steam, hammering, rushing of water, ringing of bells, ticking, crackling (bubbles in tympanal secretion), drumming," etc. With purulent middle-ear disease, compared to "the escape of steam, singing (as from quininism), hammering, ringing of bells, blowing, raining, rattling (as of machinery), humming, crackling (bubbles in pus), hissing, clock ticking, music," etc. With internal-ear disease, to "steam exhaust, escape of steam, ticking like a watch, bell ringing, rattling of machinery (generally in mill hands), steam-whistle; and there were some cases (fortunately few), in which the noises varied hourly, from "delightful music" to the "babel of an excited mob." Systolic pulsating tinnitus, with and due to the pulsation of a diseased or anæmic heart or the thrill of an aneurism of one or more great vessels (not necessarily of the head), was frequently met with, and was always aggravated when accompanied by any form of middle-ear disease.

Not a few patients were sent from a distance by graduates of the college, and after a most careful examination, were referred, with written details of diagnosis, prognosis and treatment, or else received especial care in the hospital, or while attending the daily service.

In inflation of the middle-ear by the catheter, or Politzer's air douch, *hydrobromic ether* (Wyeth's), as vapor, was found most agreeable, penetrating and beneficial, and hydrobromic acid (Squibb's) (in fifteen-drop doses in sweetened water after meals), acted most satisfactorily in relieving cerebral congestion and accompanying tinnitus.

Should this department, so recently established, be favored with a continuance of the success which has been so gratifying to those in charge, there is reason to hope that it will ere long rank with any other existing aural department, either here or in Europe.

Daily clinics are held from one to two o'clock, and are under the direct charge of Laurence Turnbull, M.D., with Dr. C. S. Turnbull as Chief of the Clinic, and Drs. L. W. Steinbach and M. H. Bochroch as assistants.

Medical Societies.

COLLEGE OF PHYSICIANS, PHILADELPHIA, DECEMBER 1st, 1880.

The session was principally occupied by the reading of a paper, by Dr. Richard A. Cleemann, as Chairman of the Committee on Meteorology and Epidemics, giving the—

Meteorology and Epidemics of Philadelphia in 1879.

He began by stating that the year 1879 was, taken as a whole, warmer than usual. the mean annual temperature having been 53.6° F., nearly one degree above the average (52.7° F.) for eight years (1872–1879); but it was in about the same proportion cooler than the preceding year, for which the mean reading of the thermometer had been 54.7° F.

The range of the thermometer during the year was through ninety nine degrees of temperature, from 3° F. below zero, recorded on January 3d, to 96° F., registered July 16th. This extent of annual variation is not exceptional, but the months individually were marked by greater differences of temperature than is usual; the average range for January is through 50° F., but this year the range was 59° F.; while in October the difference was 55° F., instead of 43° F., and in November 56° F., instead of 46° F. The first autumnal frost was observed on September 26th.

Rain Fall.—During the year 36.75 inches of rain and snow (melted) fell, the year 1879 having been like the two preceding years, deficient in precipitation. The rain or snow fell on 128 days, seven less than the average. The most rain was collected in August, as much as 7.13 inches, while for October only 0.41 inch is recorded.

Dr. Cleemann proceeded :—

The number of deaths recorded at the Health Office, in Philadelphia, during the year 1879, was 15,471. This is exclusive of the "still-born," which numbered in the same period 811, and of deaths following "premature birth," which equaled 190.

The population of Philadelphia in June of the present year (1880) was, according to the figures of the United States census, 846,980 inhabitants.

The mortality of 1879 was distributed unequally between the sexes; 7886 of those who died were males, and 7585 females, the latter sex furnishing, as usual, the lesser number.

The infantile mortality is seen to bear a large proportion to the total number of deaths, especially for the first year of life, and as much as 35.69 per cent. of the whole mortality to have fallen upon children less than five years old. Great as this proportion is, my previous reports show that it is less than it is accustomed to be, as might have been looked for in an exceptionally healthy year.

The 336 deaths from scarlatina constitute a mortality less by 218 than that from the same cause in 1878. The mortality in the latter year, it will be remembered, followed upon a large increase in the number of deaths from the disease in the last quarter of 1877, was on the decline in the third quarter of the year, and rose again in extent at the end of the year, but not to a degree to negative the inference that the disease was really decreasing, and might be expected to cause fewer deaths in 1879.

The record gives 321 deaths from diphtheria, or a mortality about a third less than in the previous year. In that year the deaths from diphtheria in the last quarter exceeded in number those in the first three months of the year, but in 1879 the reverse was the case, there being only 88 deaths in the last quarter to 130 in the first. The difference is important as regards the year 1880, the diminishing mortality indicating, as in the case of scarlatina, a decline in the disease for that year. The intermediate quarters of the year had, according to the invariable rule, a lessened mortality from diphtheria, the second furnishing 37 and the third 46 deaths.

Season made evident its accustomed influence over the mortality from croup, since of the 291 deaths credited to this cause during the year, 121 were recorded in the first quarter, only 30 in the second, with 27 in the third, and as many as 112 in the last quarter of the year. Each of these numbers is less than that for the corresponding period in the previous year, and the whole difference between the annual aggregates of mortality from this disease equals 97, or a falling off in 1879 of twenty-five per cent.

The increase over last year in the number of deaths due to cholera infantum, already referred to, was 104, the whole number of deaths caused by this disease in 1879 having been 804.

Since the year 1876, a steadily declining death rate of typhoid fever has been recorded, till in 1879 the number of deaths laid at the door of this insidious malady, 344, is the lowest in proportion to population, attained during the twenty years of reliable registration in Philadelphia. Indeed, there were only three years during this time in which, among fewer inhabitants, the zymotic claimed a lower mortality, the years 1861, 1871, and 1872.

The deaths from typhoid fever in this year of lightened mortality were divided among the several quarters of the year in a quite unusual way; 97 occurred in the first quarter, 74 in the second, 82 in the third, and 91 in the fourth. Hence the summer maximum, which I have shown in former reports to be a characteristic feature of the mortality from this disease, in Philadelphia, disappeared, overwhelmed by the increased number of deaths accruing to the first and last quarters of the year. The diminished summer mortality coincided with a temperature somewhat lower than usual at this season, joined to an excessive rain fall, and followed upon a very cold January and February; while the comparatively high rate of the last quarter was the accompaniment of an opposite condition of things, exceptionally hot weather in October, with deficient precipitation in this month and November. Though efforts are constantly being made to better the sanitary condition of the city, I cannot discover enough improvement to explain thereby the diminution in the mortality from typhoid fever since the year 1876; I have therefore been led to bring forward, as prominently as I have, the meteorological conditions upon which the fortunate change in recent years and last summer seems to have depended.

One of our fellows, Dr. William Pepper, re-

ported a case of mild but true typhus fever, which was taken into the Philadelphia Hospital in November, 1879, being the first case of that disease brought there for several years; this case was followed by several others which were received into the house. Besides these a few more were reported to the Health Office (unpublished records of the Health Office), but in only one instance, in an obscure part of the city, did death result. The disease, therefore, was not of a severe nature, and had no marked tendency to spread.

A single death from yellow fever was recorded in 1879. The victim was one of the crew of a ship which arrived from Cuba on the last day of the quarantine season (September 30th), and was permitted to come up to the wharf, the fact that a sailor had died on the voyage, of fever, having been suppressed, so that no suspicion of infection of any kind had been entertained. The disease showed itself a day or two after the ship's arrival, but, being mistaken for ordinary malarial fever, the patient was removed to a general hospital, which happened to be in the very heart of the city. Here he manifested undoubted symptoms of yellow fever, and was removed to a special hospital, where he died. Fortunately, the hot season had passed, so that notwithstanding the conditions mentioned which might have been favorable to the extension of the disease, no other cases presented themselves.

Dr. Cleeman closed his report with the pre sentation of a number of tables, meteorological and statistical.

MEETING OF THE PHILADELPHIA LARYNGOLOGICAL SOCIETY,

Held at the house of Dr. C. Seiler, 1346 Spruce street, Philadelphia, December 17th, 1880.

The President, Dr. J. Solis Cohen, in the chair.

Before organizing, Dr. McCracken exhibited a case of stenosis of the larynx, and Dr. Cohen a case of stenosis of the posterior nares, caused by complete adhesion of the soft palate to the posterior walls of the pharynx.

The meeting was then organized, and Dr. Potsdamer read an interesting paper on a case of goitre, in which he said that the case was one of peculiar interest on account of the peculiar symptoms to which the tumor in the neck gave rise, viz: vague and intermittent pains in the head and over the spleen; a spasmodic cough with an apparently normal larynx; dilatation of the left pupil and a constant flush on the left cheek; also grave derangement of the digestive system. He also stated that peculiar anatomical changes had taken place in the course of the vessels of the neck, both the jugular veins and carotid arteries being very prominent and displaced. The Doctor stated that, in his opinion, the symptoms of the case were due to pressure upon both pneumogastrics and upon the left ganglionic nerves of the neck by the enlarged thyroid gland.

The subject of goitre was then discussed by most of the members present.

Dr. McCracken next gave the history of the case of stenosis of the larynx which had been examined by the members before the meeting, as follows: H. H., aged 12 years, had an attack of acute laryngitis about four months previous, from which he speedily recovered. On September 1st he had a fresh attack, with cough, yellow expectoration, loss of strength and flesh. He became hoarse about November 1st, and a week from that time his respiration became stridulous. An examination of his chest revealed evidences of consolidation at the apex of the right lung. Family history good. A laryngoscopic examination revealed the following conditions: the epiglottis was split in the middle to about one-half of its entire length (evidently a congenital malformation) but appeared otherwise healthy; both ary-epiglottic folds, together with the arytenoid cartilages, were greatly tumefied; the vocal cords were red, glistening and greatly changed in outline; the right cord protruded considerably beyond the median line at its anterior half, while the left one presented an excavation in its edge, opposite the protuberance of the right cord; the left cord presented also a V-shaped notch in its edge near the middle. There was no evidence of any adhesion between the cords, and the stenosis was due to the swelling only. The patient had considerably improved under appropriate treatment. This and similar cases were discussed by several of the members.

Dr. Cohen then stated that the case of stenosis of the posterior nares, which had been examined by the members, was one in which the loss of the uvula and the complete agglutination of the soft palate to the wall of the pharynx was due to inherited syphilis, and that an operation was contemplated to relieve the stenosis, which seemed to be the only inconvenience the patient complained of. The voice and articulation were normal, with the exception of the letters "m and n," which the patient could not pronounce. In the discussion which followed, Dr. Seiler showed some drawings made from a case similar to the one exhibited by Dr. Cohen. In this case there was not a complete stenosis of the posterior nares, but a communication existed between the nasal and oral cavities in a small orifice on the left side. A curious feature in the case was the destruction of the right side of the epiglottis down to the glosso-epiglottic folds and of the ary-epiglottic fold, together with the top of the arytenoid cartilage on the same side, due to congenital syphilis. In this case the voice as well as deglutition were normal, but articulation very nasal, on account of the continuous communication between the oral and nasal cavities.

C. Seiler, *Secretary.*

The Oral Method for Deaf-Mutes.

The International Congress on the Education of the Deaf, held at Milan in September last, declared that, considering the incontestable superiority of speech over signs in restoring the deaf-mute to society, and in giving him a more perfect knowledge of language, the oral method ought to be preferred to that of signs for the education and instruction of the deaf and dumb. The Congress further declared that, considering that the simultaneous use of speech and signs affects, prejudicially, speech, lip-reading, and precision of ideas, the pure oral method ought to be preferred.

Treatment of Ulcers.

In a report of work in the Cardiff Infirmary (*Lancet*, November 13th) Dr. A. Sheen, says—The usual treatment of ulcerated legs has been rest in bed on an inclined board, cleanliness, bandaging, in some cases strapping, and various local applications, according to circumstances—carbolic oil, lotio rubra, boracic ointment, zinc ointment, etc. One is well repaid by directing a little attention to these local applications; indeed in this, and in other directions of treatment, we are far too apt, from the cases being so common and so numerous, to lapse into a system of careless routine, which is anything but beneficial to the patient. Carbolic oil is a useful early application in some cases, but it must be borne in mind that it delays cicatrization, and when it has served its purpose, some other application, as lotio rubra, which is most useful in aiding granulation and cicatrization, should be resorted to. Boracic ointment is a valuable application in some cases, and acts admirably as a deodorizer of foul discharges, or rather as a preventer of their becoming foul. I have not yet treated ulcers on Lister's antiseptic method, but intend doing so; Martin's elastic bandage has been chiefly of value in the varicose variety; in such cases it answers admirably. Where there has been any constitutional dyscrasia, obvious or suspected, internal treatment has been adopted to aid the cure. If eczema is present, arsenic has been given with advantage; and so also opium, where pain is a dominant symptom. When the ulcer is specific iodide of potassium acts often like magic, and where there is any suspicion of such connection it is wise to give it, to aid the diagnosis. In some cases it clears up matters wonderfully. I have known cases which after being under various kinds of treatment for a lengthened period, have healed up in a week or two, under iodide of potassium and simple dressing. On the healing of varicose and some other ulcers, if you have an intelligent patient to deal with, I strongly approve of an elastic stocking being worn, but it should be adapted before the patient leaves the hospital, to ensure its fitting properly, and he should be cautioned about its proper use. In almost all cases, under rest, good and regular diet, and the avoidance of all irritating applications to the ulcer (which, as a rule, have been pretty freely applied before the patient's admission), rapid improvement is observed. In some cases of indolent ulcer, blistering has been followed by beneficial results. The application of a splint has sometimes been of value by keeping the parts at rest, and one obstinate case, where the ulcer was situated at the lower part of the back of the leg, was cured by relaxing the tendo-Achillis by means of a slipper, and a strap extending from it to above the knee. The practice of skin grafting has been adopted in suitable cases, and the results in some of them have been everything that one could desire. The heel case was chronic and extensive, the result of injury a long time previously. The patient had been unable to work for five or six years, and craved to have the foot removed. Amputation in the lower third of the leg, taking a long anterior flap, was perform d antiseptically, catgut ligatures and sutures b ing used; the stump was dressed four times; the temperature was normal throughout, and in eighteen days the patient was up, being discharged with an admirable stump ten days later. One case of scrofulous ulceration of the face was attacked by erysipelas, and this case showed the value of aconite in small and frequently repeated doses in this disease, for, under its use, in two days the temperature was normal. Nitrate of silver, four grains to the drachm, was applied, to see if it would stop the erysipelas from spreading. It did not have this effect, neither did I expect that it would. Aconite in small and frequently repeated doses, as advised by Ringer, will, as a rule, in such cases, meet all the indications, without any other treatment, general or local.

Chloral in After-pains.

The following case is reported by Dr. Julia Carpenter. She says: I remained with the patient three hours after the birth of the child. During this time there were some after pains, which toward the last were severe enough to require relief, so the following was prescribed:—

℞. Morphiæ sulphat., gr.ss
Aquæ camphoræ, ℥j.

Sig.—Teaspoonful every half hour, if needed, until three doses are taken.

Called again at eight o'clock P.M. Patient had had severe pains every fifteen minutes, but at that time they seemed to be getting under control. At one o'clock at night they came for me, saying the paroxysms were so violent they were alarmed; all the medicine had been taken and still no relief was afforded.

Knowing that the good recovery of this patient depended on the amount of nourishment she could take, no more remedies were given per os. Suppositories of one grain of opium were substituted, and flannels wrung out of hot water were constantly employed, a fresh one with every pain. This would always check a pain, but not prevent its recurrence. I remained with the patient until nine o'clock in the morning, when she seemed to be gradually getting relief. On returning at three o'clock, I found, though four suppositories in all had been used, and hot flannel constantly applied, the pains had returned with great violence.

I now concluded to try the efficacy of a small dose of chloral, without the patient's knowledge, as she had asked not to have it given her, and by enema, eight grains of chloral, in half an ounce of glycerine and water, were taken. The relief was *instantaneous*. "Oh! I'm so comfort-

able," was her immediate expression. Not one more pain returned, and the following night was spent in sound and refreshing sleep.

During the hours of severest contractions the flow ceased almost entirely, and no clots passed at any time. Twenty-four hours after the birth of the child the uterus was more than half way below the umbilicus, and subsequent to the relaxation from the chloral, there was a barely appreciable increase in size. The patient made an excellent recovery.

A Case of Poisoning with Ergot.

Dr. M. F. Leary reports this case, which is of interest, as some claim ergot is not a poison. It is from the New Orleans *Medical Journal*, December:—

November 12th, at an early hour in the morning, I was summoned to Mrs. W., and found that she had aborted, an hour previous, a three months' fœtus, with but an inconsiderable hemorrhage. The membranes had come away, the external os was patulous, but the uterus quite firmly contracted. The lady had borne two children to full term, and this was her first abortion. She had been in poor health for a year, dating from an attack of acute rheumatism. As there was still some flowing, I administered a small dose of ergot, and after remaining an hour left her to attend another call, her pulse and general condition being perfectly satisfactory. While at the house I prepared a soporific and left it with her husband, with directions for its use, and later I discovered that I had forgotten my case vial containing ergot, but being pressed for time did not return for it. Two hours after leaving Mrs. W., I was again summoned to her bedside, to find her pulseless, her skin blanched and the extremities cold. The action of the heart was very feeble and rapid, the breathing slow, but not labored. She complained of a buzzing sound, very distressing, in her ears, and appeared somewhat stupid, but otherwise her mind was not affected. There was no nausea or tendency to syncope when in a recumbent position. An examination revealed the fact that there had been no flowing during my absence. The entire uterus was firmly contracted, and was the seat of considerable pain. On inquiry I learned that the husband had mistaken my ergot vial for the one containing the soporific, and had given his wife teaspoonful doses of its contents every half hour till it was empty. She had, therefore, taken half an ounce of Squibb's extract of ergot. He stated that her pains (of which she was quite free when I left her) came on shortly after taking the first dose, and that each succeeding dose seemed but to aggravate them; that the symptoms of collapse set in very suddenly after the last dose, some twenty minutes before my arrival, that she had taken nothing else, with the exception of water, and had not moved from the position in which I left her. I was fully convinced that her condition was produced solely by the ergot, and this conviction was strengthened by noting its powerful action on the uterus. Satisfied that the ergot had "done its worst," I assured her friends of her safety, and employed only frictions and heat to the extremities and small quantities of wine per orem, at intervals. In the course of three hours there was a sensible pulse at the wrist, but it was fully nine hours before it had recovered its volume previous to taking the ergot. The reaction was attended with a slight fever, but no other unpleasant consequences resulted, and she had a rapid getting up.

Treatment of Aural Polypi.

The Glasgow *Medical Journal* states that Professor Politzer recommends rectified spirit of wine as the best remedy for polypus or granular growths in the outer or middle ear, as more certain in action, and involving fewer disadvantages than solutions of acetate of lead, muriate of iron, &c., so commonly used. The ear must first be cleared of secretion by injection with lukewarm water; if there be suppuration of the middle ear the Eustachian tube must be inflated, to drive the pus into the external meatus. The parts should then be carefully dried. The head is then to be turned over to one side, and a teaspoonful of slightly warmed spirit poured into the ear, where it is to be allowed to remain ten to fifteen minutes. This is done three times daily. The spirit produces a slight burning sensation in the ear; if acute pain be excited, weaker solutions must at first be used, then the stronger preparation. The alcohol first whitens the granulations by coagulating the mucus which lies on the surface; it subsequently penetrates the tissues, produces coagulation in the vessels, and so leads to the shrinking of the new formations. The time occupied by the treatment varies from a few days to several weeks, occasionally months. The soft, round-cell polypi yield most rapidly, the firm, fibrous kind more slowly; nevertheless, many, even of the latter variety, disappear completely, and leave no trace behind. Politzer has used alcohol in the above way for two years, and gives the following as the conditions in which it will be found most useful:—

1. In the treatment of the remains of polypi, which cannot be removed by operative means, and which are situated in the outer auditory meatus, on the membrana tympani, or more particularly in the tympanic cavity.
2. In cases of multiple granulations in the external ear, and on the membrana tympani.
3. In cases of diffuse hypertrophy of the mucous membrane of the middle ear.
5. In cases in which the removal of the growths by instruments is prevented by mechanical obstacles in the external meatus.
5. In the treatment of children and nervous patients, in whom an operation could be undertaken only with the aid of anæsthetics.
6. In otitis mycosa.

New Theory as to the Pathological Changes in the Blood in Acute Rheumatism.

At a meeting of the Cambridge Medical Society, reported in the *Lancet*, November 13th, Professor Latham advanced a new theory as to the pathology of acute rheumatism. He maintained that the first step was a lowering of the action of the "inhibitory chemical centre," or

nervous centre, which controls oxidation in the muscular tissue. Following upon this, the oxygen from the oxyhæmoglobin, instead of entering the muscular tissue to be exhaled therefrom in the form of carbonic acid gas, had its sojourn in the tissue shortened, and passed into the blood in the form of lactic acid (a substance which appears in muscle almost instantaneously with its death); that the oxygen acted also more energetically on the muscular tissue, and the resulting lactic acid being oxidized rapidly in the blood, instead of in the muscular tissue, an abnormal amount of heat or pyrexia was developed.

He then argued that quinia lowered temperature by simply impeding the carrying of ozone from the lungs to the tissues by the red blood corpuscles, as in Binz's experiments with ozonized turpentine and guaiacum; and so the remedy might act beneficially in rheumatism, but would have no effect on the *materies morbi*. Salicylic acid, on the other hand, lowered the temperature and cured the disease by chemically combining with the substances from which the lactic acid is derived, and producing less heat than would result from the oxidation of that substance. He showed how the theory advanced explained the relapses which so often recur after apparent cure with salicylic acid, the necessity for large doses of the remedy, and the reason why it should be less curative in other pyrexial disorders, such as pneumonia, typhoid fever, etc. Referring to locomotor ataxy as an example, he suggested that possibly the local symptoms might be the result of the lactic acid acting upon the posterior columns of the spinal cord, producing functional change; and, in reply to a question in the discussion afterwards as to the connection between rheumatism and chorea, considered that this disorder was the result of the lactic acid inducing functional change in the nervous centre which co-ördinates muscular movement, that centre being weak, and therefore a point of minimum energy, and this condition being hereditary or acquired. He also applied his theory to explain why the same cause (cold), which in one person appears to produce acute rheumatism, in others produces pneumonia, tonsillitis, etc.

Epileptiform Convulsions Successfully Treated by Hypodermic Injections of Sulphate of Atropia.

Dr Thomas Legare, of Charleston, S. C., sends us a report of several cases of this kind, one of which we quote:—

I was called in consultation, while practicing in the town of Orangeburg, S. C., to visit G. B., a man in the prime of life, aged thirty-five years, tall, well-developed, and of a seeming robust constitution. He was in a most critical condition, having had paroxysm after paroxysm of the most violent epileptiform convulsions for the preceding three days, numbering, approximatively, thirty to forty in the twenty-four hours. History of case as follows: Patient always enjoyed good health; a short time previous to his recent illness he became involved in a difficulty, and received a blow across the left supra-orbital ridge, cutting the skin to the bone; for four or five weeks he suffered from the effects of this injury, when the wound healed, leaving a very perceptible cicatrix over the left eyebrow. Shortly after the wound had cicatrized severe epileptiform convulsions developed. On our first visit to the patient, three days subsequent to his having received medical attention, we found him laboring under a severe convulsion. Upon inquiring into the treatment that had been pursued, learned that very nearly every remedy recommended in this disease had been used, the patient not having received the slightest benefit; bromides in large doses had been given; belladonna, combined with hyoscyamus, nitrite of amyl, and chloroform inhalations, blisters, cathartics, and the sulphate of quinine in sedative doses, all had failed, leaving the patient more and more exhausted. It was at this period of the treatment that we determined to use an agent which would be at once prompt and efficient in its action—the sulphate of atropia; it was therefore administered, one-twenty-fourth of a grain in ten minims of water being injected under the skin of the forehead. In a few seconds the effects of the injection were very apparent; patient complained of thirst, dryness of throat, and an uncomfortable feeling about the head; pupils of the eyes at the same time were widely dilated; in a short while, all these disagreeable sensations passed off; and on our next visit we found the patient considerably improved, having passed twenty-four hours without the occurrence of a single convulsion. The attending physician being called away, I continued the treatment. Another injection of the same strength was administered, and upon visiting him twelve hours afterward no return of the convulsions had occurred; continued injections twice a day, morning and evening, for three days. The attending physician returning, we then decreased the dose to one-thirtieth of a grain; patient had a slight convulsive seizure same evening, the first he had had since the commencement of the injections; persevered with the injections twice a day, for two weeks, at the end of which time there being no return of the convulsions, and patient expressing himself well and desirous of going to work, treatment was discontinued, and the case discharged—cured.

The True Mechanical Theory of the Forceps.

Prof. Stephenson, of the University of Aberdeen, read a paper, lately, before the Obstetrical Society of London, on the rotatory action of the forceps. He stated his opinion that recent modifications in forceps showed that the inventive faculty still moved in the grooves of the older and more imperfect ideas. The sole idea was how may we, with the head tight in the grip of the blades, draw with greater accuracy in a given straight line. What really is wanted is an improved form of the instrument which will enable us to impart more readily the rotary movements which we observe in nature. The division of the traction from the prehensile blades weakens the transmission of information by the handles to the hand of the operator; in his muscular and tactile sense should reside the true "indicating needle." The claim made for Tarnier's forceps, that they

allow freer movement of the head in all directions, is no more true than applies to the ordinary instruments, if the operator attends to the directions, which they supply. The opponents of the pendulum movement with forceps occupy good ground when they show it is contrary to the normal mechanism and a fortuitious and risky mode of action; but they go too far when they include in their condemnation all so-called lever actions. The true defence of the lever action is to throw out all that is hap-hazard, and give it scientific precision. The term "lever action" is objectionable, "rotary action" is preferable. The forces of labor cannot be reduced to a single resultant, but always consist of a resultant and a couple, the former moving the head inward the latter imparting some movement of rotation. With forceps we have the power of producing both movements; and as in nature they are always combined, so in art they should never be entirely separated. With the inward traction made in the axis of the pelvis must always be combined such a movement of the instrument as will tend to impart to the head the rotary movement, which observation teaches us takes place at that particular stage of mechanism. 1. Flexion and extension. With the head in the firm grasp of the forceps, especially if screwed up, there is a tendency to bring down both ends of the head through an equal space, and so prevent due flexion from taking place. But, on the other hand, if the blades are applied with a diagonal grasp, the compressing power of the forceps may be made to promote flexion. But flexion or extension must chiefly be promoted by a modification of the rule of traction, which might be thus stated: While the force should always be exerted with strict reference to the direction of the axis of the pelvis, the line of traction should be in a slightly curved direction, the curve passing out of the line of the axis in a direction corresponding to that of the sagittal suture toward the side where the forehead lies for flexion, to the side on which the occiput is for extension. 2. The rotation of the occiput forward might also be promoted by rotating the forceps on their axis, and bringing the handles slightly toward the side on which the occiput lies. The grasp must be light, so as to permit gliding between the blades. 3. As the head passes under the pubic arch the rule should be that while carrying the handles forward to ward the front of the mother, a carefully applied slight rotatory action should be imparted to the forceps, so as to facilitate the change of the sagittal suture from lying oblique to approach near to that of the mesial line. Rotation in narrowed pelves. The application of forceps tends to rotate the head from a transverse to an oblique diameter, and the frontal bone is liable to be thereby thrown on to the promontory. Hence the following rule: When the occipital bone has descended below the level of the brain, and is felt directed against the anterior wall of the pelvis, in order to clear the forehead and prevent injury of the frontal bone the head should be rotated on a vertical axis, so as to throw the frontal bone off the promontory, and at the same time slight extension should be given to the head to bring the fore part down at the side of the pelvis.

Eucalyptus Oil in Antiseptic Dressings.

Dr. Siegen writes very favorably (in *Deutsche Med. Wochenschr.*, 1880, No. 30), of oil of eucalyptus as an antiseptic, its special advantage being that it shows no tendency to cause eczema or to irritate the skin in any way. The solution employed by Siegen was made by dissolving 3 grams of the oil in 15 grams of alcohol, and adding 150 grams of water; this quantity is enough to moisten thoroughly one meter of well-washed gauze. The dressing is applied wet, and covered with gutta percha tissue; it may remain without changing for 3–5 days. It is noted that in one case an eczematous eruption, which had been caused by a thymol dressing, healed under the eucalyptus dressing in a few days.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a reprint sent us, Dr. S. Theobald, of Baltimore, mentions some of the errors in the diagnosis of eye diseases into which general practitioners are most apt to fall. Probably the most common is the confounding of catarrhal with phlyctenular or scrofulous ophthalmia, and as a consequence the use of astringents when atropia and yellow oxide of mercury are indicated, and, latterly, of atropia when astringents should be employed. The best way to avoid this mistake, which may lead to serious consequences, is to bear in mind that in catarrhal ophthalmia the cornea is not involved, the redness is diffuse, and there is but little photophobia or lachrymation; whereas in scrofulous inflammation the cornea is involved more often than not, there is usually great photophobia and lachrymation, and the redness, if not literally circumscribed, is at least more pronounced in the neighborhood of the phlyctenulæ.

——A well-prepared article on the pathology and treatment of Epulis, by Dr. N. Sann, of Milwaukee, appears as a reprint from the *Dental Cosmos*. He is of opinion that thorough extirpation by excision is the only safe procedure.

——Dr. Clifton E. Wing, of Boston, in a pamphlet sent us, attacks the "abdominal method" of singing and breathing, and accuses it of being a frequent cause of female weakness. He observes:—

That serious uterine troubles should be caused in this way will not, therefore, surprise physicians once informed of this method and the manner in which it is practiced at the present time. I am assured by good authority that one Boston teacher boasts that by "*proper practice*" such power may be acquired that if the person be

placed back against the wall and a full-sized piano be moved up against the retracted abdomen, the latter, by the "abdominal method," can be so forcibly expanded that the piano will be pushed rapidly away. A medical education is hardly necessary to enable a person to understand that by such procedures injurious pressure must come upon the internal organs, especially in the female.

——In a reprint from the *Archives of Laryngology*, Dr. Beverly Robinson emphasizes the therapeutic value of rest in the treatment of laryngeal diseases. He concludes his observations with this expression:—

Whenever and wherever we are called upon to treat laryngeal troubles, let us bear in mind that the production of physiological rest is the curative principle upon which most of the good effects attributable to other means—medicinal, surgical, hygienic—in the main depend, and we shall then be willing to give to it its genuine value.

——Part VIII of Dr. Duhring's Atlas of Skin Diseases has appeared. It contains illustrations of eczema, psoriasis, syphiloderma and tinea. The plates are finished with the great care which has characterized them all. We repeat what we have previously said of the very high character of this atlas. Nothing that has been heretofore produced in this country equals it. Both dermatologists and general practitioners who wish such a publication cannot fail to be satisfied with it.

BOOK NOTICES.

Differential Diagnosis: A Manual of the Comparative Semeiology of the more important Diseases. By F. DeHavilland Hall, M.D., assistant physician to the Westminster Hospital, London. Second American edition, with extensive additions. Edited by Frank Woodbury, M.D., etc., Philadelphia. D. G. Brinton, 115 South 7th St., Philadelphia, 1881. 1 vol. cloth, 8vo., pp. 223. Price, $2.00.

The work of Dr. Hall has met with a very appreciative reception in America. Prepared at first with the intention of presenting in the clearest, most unmistakable form the differential diagnosis of thoracic diseases, and afterwards extended to all the more important maladies, it found both in England and the United States a ready market. It was of that character that, when one would buy it, he would recommend it to a friend; when one would pick it up in a neighbor's office, he would want a copy for himself. Hence, its distribution was rather through its merits, than the effect of the advertising it received.

For nearly a year it has been out of print in this country. The present edition has been thoroughly and ably revised by Dr. Frank Woodbury, whose literary skill and qualifications for the task we need not dwell upon, as they are well known from his edition of Farquharson's Therapeutics and numerous original contributions to professional literature.

There have been considerable additions made to the former edition, and in many places the text has been completely re-written. The chapter on the nervous system—that part of our organization about which we know so little and write so much—is almost altogether new. It fully and clearly represents the most recent views, so far as the differential diagnosis of the diseases of these obscure tissues and functions is known.

To those who are not acquainted with the character of Dr. Hall's work, we may say that its special field, as indicated by the title, is *differential* diagnosis; it aims to set forth, first, the general comparative signs and symptoms of disease, laying special stress on the *pathognomonic* symptoms; secondly, the early and often overlooked symptoms, but such as, if closely scanned, will often justify a diagnosis; and thirdly, the *peculiar features* which diseases assume in the United States. The last is, of course, the work of the American editor.

In following out this scheme the tabular method has been freely made use of; not to the exclusion of ordinary text, by any means, but only where a natural contrast exists, and in order to bring this more clearly and directly to the mind of the reader. This method, thus employed, has all the advantages of a chart or map, speaking to the eye as well as to the mind, and enabling the reader, at the least possible expenditure of time and labor, to refresh his memory as to the characteristic differences of diseases simulating each other.

The classification of diseases adopted is that now generally preferred, being based, with few alterations, on the nosology recommended by the London College of Physicians some years ago.

The paper, printing and binding of the book are of good character, durable and neat, and the price at which it is put is lower than most works of its size.

Transactions of the Medical Society of the State of West Virginia. Wheeling, 1880.

Transactions of the Medical Society of the State of North Carolina, 1880.

The volume from West Virginia gives the Minutes of the 13th annual meeting of the Society, and adds the papers read before it. The latter

embrace a report of a case of ovarian tumor, by Dr. B. W. Allen; on the treatment of typhoid fever, by Dr. A. H. Kunst; on the operation for vesico-vaginal fistula, by Dr. H. N. Mackey; on the relations of meteorology and disease, by Dr. E. A. Hildreth; and surgical cases and epidemics, by Dr. John Frissell. The last mentioned paper has unusual historical interest, as Dr. Frissell speaks from personal observation, extending over nearly half a century, in his locality (Wheeling). He adds some suggestive reflections on the etiology of epidemics, as, for instance, he says:—

Dysentery has, I think, occurred most often in limestone districts, where the water is strongly impregnated with lime; it has most prevailed in these localities in *very dry seasons*, when, as we may suppose, the proportional amount of the calcareous ingredient of the water would be increased. The limestone regions and the lime water are also favorable to the formation of stone in the bladder.

There is less original matter in the North Carolina volume. The papers read before the meeting were mostly summaries and reports of progress. It may be a question whether this kind of work merits publication in a volume of transactions, however meritorious it may be in itself. The collection of extracts from journals and books should rather remain with medical periodical literature. The original articles in the volume before us are, one on pelvic cellulitis, by Dr. Thomas J. Moore, who goes quite thoroughly into the disease, but rather from authorities than from personal observations; on quarantine, by Dr. E. A. Anderson; and on hip-joint disease, by Dr. J. D. Roberts, who is principally occupied in presenting the merits of Sayre's hip joint instrument. In fact, we say with regret, that there is not a single article based on personal investigation in the volume. Why do not medical writers and essayists learn that a single, ordinary case of disease, thoughtfully studied and accurately reported, is of more value to the reader or hearer, than fifty pages of culling from the library shelves, no matter how thoroughly the latter is done? This criticism is not, by any means, applicable solely to the volume before us. It is no more censurable in this respect than are many, nay, most others of its class; it has only been taken as an example, and we could wish, as an example to be avoided in future.

Ringworm, its Diagnosis and Treatment. By Alder Smith, M.B., London. Phila., Presley Blakiston. 12mo., cloth, pp. 81. Price $1.00.

Tinea is a notoriously troublesome disease to deal with, hard to drive away and harder to keep away. Hence, we believe many will be glad to read this monograph, written by a competent dermatologist, who for ten years has given a great deal of special study to the disease. He speaks of it both as it occurs on the head and on the body. The last chapter, "Ringworm in Schools," will be to many worth getting the book for. We would say of the monograph, that it is sound, instructive and altogether satisfactory.

Manual of Ophthalmoscopy. For the use of Students. By Dr. Daguenet. Translated by C. F. Jeaffreson, F.R.C.S.E. Phila., Presley Blakiston. 1 vol., cloth, 12mo, pp. 243. Price $1.00.

This is a condensed epitome of the lectures of Prof. Galezowski, by one of his students. The writer has made a special effort to bring prominently forward the functional symptoms of ocular disease, as they are often sufficient in themselves to establish a probable diagnosis. Hence, less attention has been given to the strictly mechanical examination of the eye and its methods. Nevertheless, several chapters are devoted to ophthalmoscopy, sufficient to give the student a fair notion of the instrument and its uses. Most of the remaining chapters take up affections of particular portions of the organ, the optic nerve, the retina, the vitreous body, etc. The language is terse and clear, and the translation well made.

Drainage for Health; or, Easy Lessons in Sanitary Science. By Joseph Wilson, M.D., Med. Director U. S. Navy. Phila., Presley Blakiston. 1 vol., 8vo, pp. 68. Illustrated. Price, cloth, $1.00.

Dr. Wilson is favorably known as one of the leading American writers on hygiene and public health. In the present short treatise he groups together a number of the most definite and generally interesting facts, principally with a view to instructing the public, especially sanitary engineers, legislators, etc., though there is much in it most medical men could profitably read.

There are four chapters; one on land drainage a second on drainage of the farm-house and the village, a third on the drainage of cities, and a fourth, entitled "Something About Plumbing." The illustrations are numerous, and the book well printed. It deserves considerable popularity, as, no matter how much has been written on these topics of general sanitation, there is an astonishing amount of ignorance prevalent about them.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,

PHILADELPHIA, PA.

ADOLPHE GUBLER AND HIS SYSTEM OF THERAPEUTICS.

Among the losses by death to the science of medicine, few have been greater than that of ADOLPHE GUBLER, Professor of Therapeutics in the Faculty of Medicine of Paris, and Physician to the Hospital Beaujon. He died comparatively young, but had lived long enough to make a brilliant record as an observer and teacher of his branch.

GUBLER may be said to have been the most distinguished exponent of scientific therapeutics—in the best sense of the term—of this generation. Following TROUSSEAU in the professorial chair, and a pupil of that great teacher, he took a long step in advance of his master, and may be said to have developed the only method of therapeutics which reconciles the empirical and clinical art of medicine with the demands of exact and logical science. His labors created a new epoch in professional practice in France, and in all other countries where they have become known have made a profound impression on the professional mind.

He was not a very abundant writer, but what he did write was carefully worded and full of matter. His last course of lectures were reported phonographically, and having been closely revised, were published last summer in Paris.

In this work he may justly be said to present the therapeutics of modern science. He begins by almost scornfully denying that this branch is any longer an "art of healing;" it is a true science, with its own principles, methods and procedures, common to it and to physiology, of which latter it is one of the divisions. Instruments of precision and a rigorous experimental reasoning are its main aids. Remedies are no longer confined to medicaments or drugs; these are but a part of the resources at the command of the scientific therapeutist.

He sets little importance on classifications. Reviewing them one after another, he finds them all defective, the physiological plan, which he himself once adopted, as bad as any. On the vexed question of the actions of medicines he is, as always, perfectly clear. They are threefold, mechanical action, chemical action, and dynamic action, or that which leads to molecular change. There is no room for specifics, in the ordinary sense, and every medical effect is explicable by natural laws of the organism on the one hand, and of the remedy on the other. But no organism is endowed with special privileges toward a therapeutic agent. What is called *idiosyncrasy* is as much a delusion as is the entity of a disease. Every such is reducible to the influence of age, sex, habit, climate, race, heredity, and other familiar elements.

GUBLER, therefore, rejects all attempts at classifying remedies, and proceeds to consider them according to their methods of introduction into the system, as by the stomach, bladder, lungs, skin, etc.; and follows them in their transformations in the organism. With the noble candor of true science he points out where knowledge ceases and ignorance begins; but his faith in progress is unshaken; and he closes his last lecture with these words to his hearers: "Various manifestations remain which cannot yet be explained; but the science of to-day is not that

of to-morrow. My science is not yours, and you will learn to understand these phenomena in a future more or less distant."

Among GUBLER'S students and hearers were many members of the American profession. They remember well his earnest words and lucid expositions; and we believe they and many beside them will learn with pleasure that this, his last and finished, course of therapeutics has been translated, and will shortly appear. It will be published at the office of this journal, and will appear some time in February.

ANNUAL REPORT OF THE SURGEON GENERAL.

The report of the Surgeon General begins with the usual financial statistics. A statement of the work performed in the Record and Pension Division shows how enormous is the business in that office, not less than 39,241 new official demands for information having been made upon it in the year ending June 30, 1880.

The work on the surgical statistics of the war still goes on.

Through correspondence with medical officers of the civil war, from reports of pension examiners, and from surgical journals and publications, additional data were obtained in three thousand eight hundred and eight cases of injuries. Searches among the records of the Pension Office and of the Record and Pension Division of this Office gave further information in one thousand seven hundred and twenty-seven and two thousand and eighty-one cases respectively.

The work upon the Index Catalogue has been steadily carried on, and the stereotype plates of Volume I were completed in the month of July, 1880.

An edition of fifteen hundred copies of this volume has been printed and distributed, and the first part of Volume II is just going to the press.

An estimate has been forwarded for printing Volumes III and IV of the Catalogue, and it is hoped that this may be granted, in order that the progress of the work may not be interrupted.

A strong appeal is made for an appropriation for a new fire-proof building for the army medical museum and library, which we hope will not fail to receive the prompt attention it so obviously merits.

In conclusion, we give, as of general interest, the main statistics of the health of the army during the fiscal year ending June 30, 1880:—

The Monthly Reports of Sick and Wounded received up to September 15th represent an average mean strength of 22,100 white, and 2368 colored, troops.

Among the *white troops* the total number of cases of all kinds reported as taken on the sick list was 39,111, being at the rate of 1770 per thousand of mean strength.

Of this number, 33,562, or 1519 per thousand of strength, were taken on sick report for disease, and 5549, or 251 per thousand of strength, for wounds, accidents, and injuries of all kinds.

The average number constantly on sick report during the year was 986, or 45 per thousand of mean strength. Of these, 767, or 35 per thousand of strength, were constantly under treatment for disease, and 219, or 10 per thousand of strength, for wounds, accidents, and injuries.

The total number of deaths from all causes reported among the white troops was 219, or 10 per thousand of mean strength. Of these, 126 or 6 per thousand of strength, died of disease, and 93, or 4 per thousand of strength, of wounds, accidents and injuries.

The proportion of deaths from all causes to cases treated was one to 179.

Among the *colored troops* the total number of cases of all kinds reported was 4052, or 1711 per thousand of mean strength. Of these, 3581, or 1512 per thousand of strength, were cases of disease, and 471, or 199 per thousand of strength, were wounds, accidents and injuries.

The average number constantly on sick report was 89, or 37 per thousand of strength; of whom 72, or 30 per thousand of strength, were under treatment for disease, and 17, or 7 per thousand of strength, for wounds, accidents and injuries.

The total number of deaths of colored soldiers reported from all causes was 46, or 19 per thou-

sand of mean strength. Of these, 21, or 9 per thousand of strength, died of disease, and 25, or 10 per thousand of strength, of wounds, accidents and injuries.

The proportion of deaths from all causes to cases treated was 1 to 88.

Notes and Comments.

Curious Physiological Experiment.

A curious fact, and which may prove of considerable importance, was related by Dr. Brown-Séquard at a recent meeting of the Société de Biologie. Intending to kill a guinea-pig, the subject of previous experiment, the animal was placed under a glass globe with a certain quantity of ether. Anæsthesia progressing but slowly, some chloroform was poured on a sponge, which was inserted in the summit of the globe in such a position that some drops fell between the guinea-pig's neck and shoulder—that is to say, upon the epileptogenic region, when an attack of epilepsy immediately took place. The experiment which had thus been accidentally suggested was repeated a large number of times, and it was found that no longer epilepsy, but a deep anæsthesia, followed the application of chloroform. The same thing was afterwards observed in cats, dogs, and rabbits. As the anæsthesia passes off, the animal gives evidence of returning nervous and muscular sensibility; there are tremors in the four limbs. Then it tries to get up, but presents either hemiplegic or paraplegic symptoms, such as were noticed before anæsthesia took place; occasionally there is delirium, and when consciousness has returned there is a considerable degree of hyperæsthesia, and may be inflammation of the skin if the dose of chloroform has been strong. When the experiment ends fatally, death may occur, either suddenly or less quickly.

Local Bleeding in Inflammation.

Probably the advantages of local bleeding are as clearly established as those of any remedial measure known. Yet they are not supported by "laboratory therapeutics." They are, in fact, opposed by them. Lately, in order to demonstrate how useless it is to take blood from inflamed parts, Dr. E. Maragliano, Prof. of General Pathology in Genoa, performed the following experiments: The web of the foot of a curarized frog was placed under the microscope, and rubbed over with dilute croton oil; as soon as the signs of inflammation were noticed (stagnation and aggregation of the red corpuscles in the capillaries, arrangement of the white corpuscles along the venous wall), the crural vein of the other leg was opened, and a considerable quantity of blood allowed to escape. The inflammation, judged by microscopic observation, was not arrested by this proceeding; it rather became worse, and soon there was complete stasis of the circulation in the affected part. The experiment was repeated on a rabbit's ear, but in this case the blood was abstracted by leeches placed at the root of the affected ear. The result was similar; the inflammation increased in intensity, and entered more slowly on resolution than in those instances in which no bleeding was practiced. The author concludes, therefore, that the abstraction of blood, either generally or locally, rather aggravates than mitigates the inflammatory process.—(*Cbl. f. d. Med. Wiss. 20th November*, 1880.)

It is to be hoped his opinion will have no weight.

Ether and Chloroform.

In the *Lancet*, November 20, Dr. Saundby has a judicious article on these anæsthetics. He observes that inflammation of the lungs or air passages forbids the use of ether. The vapor of ether irritates healthy lungs, often to an excessive degree, and sometimes causes a slight bronchitis for a day or two, while occasionally it gives rise to fatal œdema of the lungs, even where no previous disease existed in these organs. It is, therefore, plain that all inflammatory conditions of the lungs are likely to be made worse by ether. Chloroform is to be preferred in all such cases. Cardiac disease *per se* does not contra-indicate ether, as the drug aids a weak heart. In aortic incompetence with badly filled arteries the circulation becomes better during the administration of ether. In mitral disease the case is somewhat different. It must be remembered that ether frequently causes spasmodic dyspnœa, which ordinarily need cause no alarm, and calls for nothing but temporary suspension of the administration, but during which there is great venous turgescence, and the right side of the heart is necessarily overloaded with blood. So that wherever the right side of the heart is weak and dilated one should prefer chloroform to ether. The same would hold good of dilatation of the right ventricle apart from mitral disease.

Fractures, herniæ, and other conditions in which complete muscular relaxation is required, are cases in which, *cæteris paribus*, one should use chloroform.

Operations about the face can sometimes be performed only with difficulty, or not at all, while ether is being administered; in these, chloroform must be employed.

Young children take chloroform with such ease and safety that it is to be preferred for them.

Away with the Spray.

Fort mit dem Spray!—Away with the Spray!—is the title of an interesting clinical lecture by Professor Victor von Bruns, of Tübingen (*Berliner Klinische Wochenschrift*, No. 43, for October 25th, 1880). There are now not a few earnest believers in the so-called antiseptic surgery—that is, Listerism—who are beginning to ask whether the spray is really a necessary part of a thoroughly antiseptic system of dressing wounds.

Prof. B. gives an array of statistics which he considers amply sufficient to prove that the spray is not always necessary, either during an operation or the after-dressings which it may necessitate. "For myself at least," says the learned Professor, "and, I hope, for every one who is not prejudiced, in view of the above facts, there can be no doubt of the inutility of the spray, and I consider myself fully justified in using the dictum at the heading of this lecture—'Fort mit dem Spray!'"

At a late meeting of the Royal Medical and Chirurgical Society of London, Dr. Bantock, Physician to the Samaritan Free Hospital, also denounced the spray, ascribing to the use of carbolic acid most of the pyrexial and other untoward symptoms that have occurred in cases of ovariotomy which he had performed under what he alleges were true "Listerian" precautions. He believes the severity of the pyrexia is due to the toxic effects of the carbolic acid used in the spray, and states that in proportion as he has reduced the strength of his solutions, there has been less and less pyrexia in his cases.

Effects of Tobacco on the Uterine Functions.

In a late issue of the Lyon *Médical*, Dr. Ygonin denies that tobacco is hurtful to those women engaged in its manufacture, and bases his views on his experience in the factories of Lyons. The women employed in these factories menstruate, as a rule, regularly and naturally, and do not appear to abort or miscarry oftener than other women; nor are their children more subject than other children to the diseases of early life.

Some years ago, we heard Prof. Pajot say that he had delivered occasionally women whose employment was in the large government tobacco factories of Paris. The amniotic liquid would not unfrequently be darker than natural and have a decided odor of tobacco! But he did not find either the confinements more troublesome or the children less viable than in the same class of life generally.

Special Reports.

II.—DISEASES OF CHILDREN.

The scientific activity in Pædiatrics hardly keeps pace with the demand for it, if we may be allowed to judge of the latter by the mortality reported from all quarters during the first decade of life. As always in season, we begin with some recent observations on

Pertussis.

In 1879 several English journals adduced evidence in favor of its treatment with *atropia* combined with carbolic acid inhalations. Dr. William Lee, of Baltimore, reported, in the New York *Medical Journal*, July, 1880, some successful cases thus managed. He used the atropia hypodermically, in a solution of gr. iv, to water f. ℥ j. Of this he injected one minim or more, according to the patient's age, with ten minims of water, always using it as early in the morning as possible, and repeating it at night if occasion required. The carbolic-acid solution, of the strength of five per cent., made with the very best crystals, was used as follows: five strips of Canton flannel, three inches wide and five inches long, were saturated with this solution, and hung around the patient's bed and about the room at bedtime, and they were moistened with the solution once again during the night.

As an example of its effects we quote the following case:—

Mary S., three years old, first seen August 1st, had well-developed whooping-cough. The mother stated that she had whooped fifteen times daily for the previous three days. She had particularly noticed each one because of their being so severe. One minim of the atropia solution was injected, and the carbolic acid was used at bedtime. August 2d.—Since the last note she has had ten paroxysms, those at night having been less severe. 3d.—There have been six paroxysms since the last visit—one, at night, having been very severe. 4th.—Six paroxysms have occurred, two of them very severe. The nurse had neglected the inhalations. 5th.—There have been four paroxysms, of short duration. 6th.—Three paroxysms, of very slight severity, have occurred. 7th.—But one paroxysm has occurred; very severe, however. 8th.—There have been no

more paroxysms. She is very thirsty. The treatment, which had consisted of the daily repetition of that mentioned in the first note, was now suspended. 9th.—There have been two paroxysms. Treatment renewed. 10th.—She has had no paroxysms, and has coughed but little. At the end of three days more she had entirely recovered.

Instead of using a spraying apparatus, which is not handy in country practice, Dr. E. J. Beal has suggested (St. Louis *Clinical Record*, July, 1880,) another plan, which he describes as follows, and from which he claims quite gratifying results:—

Three or four thicknesses of white flannel, four by four inches, are quilted together and suspended by tape around the neck of the little sufferer, like a necklace. The pad so formed is to be saturated three or four times daily with the following mixture, and to be worn night and day. When the child sleeps, the pad to be placed in close proximity to the respiratory outlets.

℞.	Ol. sassafras,	ʒ iij	
	Ol. terebinth.,	ʒ iv	
	Fl. ext. belladon.,	ʒ ss	
	Phenol sodique,	ʒ iv.	M.

If it is apprehended that the little sufferer will place the pad in the mouth, it would likely be well to be guarded in not exceeding the amount of belladonna suggested.

Spina Bifida.

There is a growing evidence in favor of the method of treating this affection, brought into notice by Dr. Morton, of Glasgow (1877), or, as we think is more correct, by Dr. Brainard, of Chicago (1848). A case is recorded in the Edinburgh *Journal* of October, by Dr. J. M'Watt:—

The tumor was situated over the second and third cervical vertebræ, and was fluctuating. It had a broad base, and had greatly enlarged since birth, and was now about the size of a small orange. It increased in tension on crying. The skin over it was thin-looking and livid. March 14, a small amount of clear fluid was drawn off, and two days after this, enough of the contents being removed by a canula to render the tumor flaccid, 20 minims of Dr. Morton's fluid were injected:—

℞.	Iodi,	gr. x	
	Pot. iod.,	ʒ ss	
	Glycerine,	ʒ j.	M.

On the following day slight inflammation and hardening were observed. The inflammation during the next few days gradually subsided, while the hardening increased.

April 15th. As the tumor was softening, and fluctuation could be detected, tapping was again resorted to, a tablespoonful (all that would come) of clear fluid being drawn off. In a few days afterwards 20 minims of the iodo-glycerine solution were injected.

May 15th. A trocar and canula was introduced, but no fluid came away.

June 4th. The tumor being greatly diminished in size, and quite hard, the patient was dismissed.

At a subsequent period the child was doing well, and the cure seemed complete.

Hereditary Syphilis and Rickets.

The *Progrès Médical*, of July and August last, published some lectures by Professor Parrot, upon rickets. As a cause of this disease, inherited syphilis holds an important place, and one recognized by all writers on the subject; but it has never been considered as the only cause. This, however, is the proposition which the lecturer advances: "All cases of rachitis are derived from one source—hereditary syphilis." As physician to the Hospice des Enfants Assistés, M. Parrot has an unrivaled field for observation; and although the statement is sweeping, it was probably made upon good foundation, at least, with much in its favor.

Dr. Samuel Gee gave it a qualified approval in the *Lancet*, Sept. 18, in which he has a lecture on large heads in children. He says of inherited syphilis that it enlarges the head in two ways:—

First, the characteristic enlargement is due to extensive growth of the osteophytes described by Parrot. The cranial bones, especially the frontal and occipital bones, become greatly thickened, it may be as much as two or even three centimetres. The big head, such as it is, is indicative not of a cranial cavity larger than natural, but only of a thickened skull. Wherefore the enlargement of the head from this cause is never great. Secondly, the head of syphilitic children often possesses all the characters which I have just assigned to the rickety head, and I have always deemed these children to be both syphilitic and rickety, and have even gone so far as to believe that syphilis may be looked upon as a cause of rickets.

Dr. Gee does not, however, consider syphilis as the sole cause of rickets, but as only one of many.

Although rickets is, fortunately, a disease not common in this country, the following list of essential symptoms will be of interest. They are arranged in the order of their relative frequency by Dr. H. Cripps Laurence, from an extensive observation of the disease as it appears in London, where the opportunities are ample for its study. His paper appeared in the *Medical Press and Circular*, last May:—

Essential characteristics: (*a*) Enlargement of wrists. (*b*) Sweating about the head. (*c*) Enlargement of ankles. (*d*) Convulsions *during* dentition. (*e*) Laryngismus. (*f*) Tenderness. (*g*) Rolling of the head on the pillow. (*h*) Enlargement of the ends of ribs—"beading." (*i*) Restlessness. (*j*) Spinal curvature. (*k*) Unclosed fontanelle, at 2½ years, 3 years, and 3 years

and 4 months. (*l*) Pigeon-breast, fractures. (*m*) Convulsions *before* dentition.

Dr. Laurence's object was chiefly to develop certain pathognomonic signs of the disease, and especially to point out that as enlargement of the superficial glands is a certain index of an impression made by rickets on the whole lymphatic system; so, in reference to the osseous system, "beading of the ribs" is not only an index of commencing changes in other bones, due to rickets, but, being demonstrable earlier in the ribs than in other bones, as a forerunner it is an early symptom, forearms, and thus acquires an especial relative value among the prodromata of rickets.

Nervous Diseases.

The nervous system in infancy has been the subject of some interesting investigations. Dr. Saltmann, of Breslau, has shown that the irritability of the motor nerves in early infancy is less than at a later age; the same is true of the sensory nerves, the excitability of which is below the average at birth, but increases during the first few months of life to a maximum above the average, from which it decreases to the normal (*Jahrbuch für Kinderheilkunde*, Bd. XIV).

Related to these physiological researches, is an article by Dr. H. Schmidt, in the same journal (Bd. XV) on hysteria in young children. He argues that, though rare, it is occasionally well marked, and hence is not necessarily connected with the sexual functions. He gives four cases, at the ages of seven, eight, nine and thirteen years, all girls. Although the symptoms were often severe, as violent vomiting, severe convulsions, strangling, aphonia, etc., they all yielded to a purely psychical treatment, thus demonstrating their undoubted hysterical character. These observations are important, as the possibility that apparently grave symptoms in children may be hysterical is not generally taken into account in framing a diagnosis.

Correspondence.

Remarks on Diphtheria.

Ed. Med. and Surg. Reporter.

I sit down to give my views of the nature and treatment of diphtheria. It is now generally considered, by the profession, a zymotic disease, poisoning the system and locally manifesting itself by the exudation of false-membrane on the tonsils, fauces, air passages, and when the poison is very intense, often upon abraded surfaces. The false membrane generally first appears upon the tonsils at that point which receives the impact of the current of air passing through the nasal passages on its way to the lungs. Why it is that the tonsils is the part upon which the false membrane generally first makes its appearance has often been a wonder to me, but now I have my theory to account for it. The function of the tonsils is to act as a kind of air-brake or breakwater, to break the force of the current of air before it reaches the larynx and air passages, and at the same time to act as a kind of warming pan, as my friend, Dr. McKinney, of New Brighton, Pa., suggests that I should call it, to the air before it enters the lungs, thus protecting them from the hurtful effects of cold. The tonsils, thus acting as a pillar upon which a current of air is broken up at each inspiration, and at the same time, acting as a kind of warming pan to the air before it enters the lungs, must necessarily be richly supplied with veins, arteries and nerves, else their vitality would speedily be imperiled by those depressing agents. While my theory of their function would lead to this conclusion, anatomical investigation confirms it. The distribution of blood vessels and nerves to the tonsils is perhaps richer than to any other organ of the same size in the human body. Now, when the vitality of the blood is impaired by the diphtheritic poison, then, in spite of the amount of blood supplied to the tonsils, their vitality is lowered below the point where their function can be healthfully performed without detriment to their own structure. The rapid change and disintegration going on in the tonsils, and particularly in their mucous membrane, is not replaced by healthy tissue or membrane, but by tissue having less vitality. That which takes the place of the healthy mucous membrane being called false membrane. This is why we have false membrane on the tonsils, in mild cases of diphtheria, before the disease is manifest locally in any other part of the body. The air, loaded with the zymotic poison, comes forcibly in contact with the tonsils before entering the lungs. So that, aside from the depressing effects of the cold, this part of the tonsils is more thickly sown with the germs of the disease than any other part of the body. In severe or malignant cases of the disease, false membrane may appear on any part of the body denuded of its cuticle. Still, it is an open question with me, whether, even in the most malignant cases, the tonsils are not first affected. The diphtheritic poison once having entered the system in sufficient quantity to cause a deterioration of the blood, all the tissues of the body are not as well nourished as in health, and there is a rapid increase of worn-out material and material unfit for use in the economy. This worn-out and unfit material must be eliminated from the body through the excretory glands and organs, else the cumulative effects of the poison and impurities in the blood will soon culminate in the death of the patient.

Now, if my theory is correct, the proper treatment is obvious and rational. First, stimulate the parts whose vitality is depressed below the point where healthy tissue can be reproduced. Second, stimulate the emunctories, so that the impurities of the blood and other worn-out material may be eliminated as fast as formed; and third, stimulate and sustain the system until the first two ob-

jects are achieved. If this can be done, the patient will get well, otherwise not.

Having given my theory and plan of treatment, it will next be in order to come down from generalities to particulars, and give my particular remedies and the method of their administration in the treatment of diphtheria. The excretory organs should be stimulated to their utmost capacity, if necessary, in order that the impurities of the blood may be eliminated as fast as formed, not only the worn-out material circulating in the blood, the natural result of the wear and tear accompanying functional activity of the organs—not only the increased excretory material resulting from the diphtheritic poison circulating in the blood, but *also* the excretory material of those animalcula which are supposed to be the cause of the disease. I dwell upon the necessity of doing all that is possible to keep the blood free from impurities of all kinds, because I think it is an important part in the treatment, not only of diphtheria, but of *all* diseases, a part too often neglected or overlooked by the general practitioner. This is to be done by diuretics, diaphoretics, cathartics, etc. Every physician has his own preferences in regard to particular remedies, and it is well to leave him free to choose those which his own experience leads him to put the most trust in, no matter what remedies he uses, so he keeps clearly in mind the object to be achieved and achieves it. The same might be said of the other two objects to be attained—viz., the stimulation and support of the system and of the parts whose vitality has been lowered.

When first called to see a patient sick with diphtheria, I direct that the bowels be properly evacuated. The cathartic is prescribed to meet the general indications, not as a *diphtheritic* cathartic, if I may use the expression; after the bowels are evacuated, or before, if the case is urgent or the general indications do not forbid, I prescribe a sedative, diuretic and diaphoretic, in the form of the original Dover's powders or as follows:—

℞. Pulv. ipecac, ℈ ss
Potass. nit., ʒj. M.
Ft. pulv. x.

Sig.—One every two or three hours.

Or a stimulating diuretic and diaphoretic, in the form of hot water, whisky, and sweet spirits of nitre flavored to suit the taste, and duly proportioned to meet the indications. Give it hot, sweet, and stimulating enough to slightly inebriate, and it will rarely fail to produce profuse diuresis and diaphoresis. While prescribing energetic remedies to stimulate the excretory organs we need not be idle in regard to what might be called specific treatment, anti-zymotic. Apply freely to the parts covered with false membrane pure carbolic acid liquefied by heat. This application acts not only as a stimulant to the parts, but as an anti-zymotic, the vapors from it being inhaled, and possibly a little mixed with the secretions from the parts is ingested. This application, when the tonsils are only covered with false membrane, protects the parts most exposed to the zymotic poison, as with a shield, preventing any further deposit or absorption. The throat, or I should say the parts covered with false membrane, should be mopped, swabbed or penciled, once a-day or two or three times a-day, just as the severity of the case would appear to demand it. Don't be afraid to give the carbolic acid *in its purity*. It never burns deep, and the pain from its application does not last long. In one severe case, where my resolution almost gave way, on account of the little sufferer's struggles and pitiful cries, the mother of the child, who had just recovered from the disease under similar treatment, encouraged me to persevere, because the application, though painful for a time, was followed by such lasting relief. In this case, as in all my other cases where the same course of treatment was carried out, the patient recovered. Having thus closed or repaired the breach in our line of defence, the next step is to overcome and expel that part of the enemy's forces already within our works, and assaulting the very citadel of life. To do this we must strengthen the powers or resources of defence by giving stimulants, nourishing food, and securing a sufficient amount of refreshing sleep. At the same time do not forget to keep the excretory organs at work. For internal medication, I prefer a preparation something like the following:—

℞. Potass. chlor., ʒj
Tr. ferri mur., ʒss
Alcohol, ʒj
Syr. simplic., q.s. ut ft. ʒiv. M.

Sig.—Take a teaspoonful every two or three hours, in a little water.

This plan of treatment perseveringly adhered to, and faithfully carried out to the end, will, I believe, in the vast majority of cases, if not in all, restore your patient to health, build up your reputation as a skillful, fearless and successful practitioner, and last, though not least, fill your pockets with substantial tokens of your patient's appreciation of your services.

H. Nye, M.D.

Enon Valley, Pa., December 20th, 1880.

Ovarian Dropsy.

Ed. Med. and Surg. Reporter:—

The following report of a case of ovarian dropsy was presented by A. E. Bigelow, M. D., of Barre, to the Vermont State Medical Society, at its annual meeting in October last. Being somewhat remarkable, on account of its duration, nearly twenty-eight years, the number of operations performed, and the quantity of fluid taken away, it seemed to me to be of sufficient professional interest to ask a place in the columns of your widely-circulated journal. The statements made are entirely reliable.

L. C. Butler, M.D., *Secretary.*

In June, 1853, I was called to see Mrs. Ira Holden, aged 42, a strong, muscular woman, the mother of six children at that time. During the preceding two or three years I had treated her for occasional attacks of vomiting. These paroxysms occurred from three to four times a year and lasted from twelve to twenty-four hours.

The fluid vomited would equal about twelve pounds, or a Shaker pailful, and on standing assumed a thick, semi-gelatinous appearance, color dark green. At this time I did not find her vomiting as usual, but diagnosed ovarian dropsy and removed sixteen pounds of fluid similar in character to the fluid vomited previously. In November following I drew off nine pounds, making a total for the year 1853, of 25 lbs.

In 1854, at 3 operations I removed,				28½ lbs.
In 1855, at 6	"	"	"	53 "
In 1856, at 3	"	"	"	26 "

January 15th, of this year, I removed 6 lbs, and in Februrary she gave birth to a seventh child, a healthy daughter, and no further operation was necessary until September following.

In 1857, at 6 operations there were				45 lbs.
In 1858, at 7	"	"	"	46½ "
In 1859, at 10	"	"	"	77¼ "
In 1860, at 10	"	"	"	99½ "
In 1861, at 7	"	"	"	66¼ "
In 1862, at 3	"	"	"	106 "
In 1863, at 4	"	"	"	96¾ "
In 1864, at 4	"	"	"	82¾ "
In 1865, at 3	"	"	"	74 "
In 1866, at 6	"	"	"	124½ "
In 1867, at 9	"	"	"	91½ "
In 1868, at 8	"	"	"	94¼ "
In 1869, at 8	"	"	"	96¾ "

During twenty-seven years and three months there were 278 operations, removing 5096½ lbs, an average of 18⅓ lbs at each operation. Allowing a pint for a pound, we have a total of 2548 quarts, or 637 gallons, and at thirty gallons to a barrel, we have 21 barrels and seven gallons, being more than double the quantity reported in the famous case in Dr. Watson's *Practice of Medicine.*

The patient died September 2d, 1880, and on the day following an autopsy was made, Drs. Chamberlin—who has attended her for several years past—Braley, Worthen and myself being present.

We found the sac connected with the right ovary occupying a large portion of the abdominal cavity, and firmly adherent to its walls, and attached by a strong fibrous band to the serous covering of the stomach. The upper portion of the sac had a hard, schirrous appearance, and a similar substance was found on the sides and at its lower portion. Connected with the left ovary, we found a cyst containing two pounds and fourteen ounces of clear liquid. The abdominal organs and uterus appeared healthy.

A. E. Bigelow, M.D.

Recovery From Severe Burn.

Ed. Med. and Surg. Reporter:—

Allow me to call the attention of your numerous readers to a case of severe burn, with recovery, under conditions eminently unfavorable.

On the 26th of May last I was hastily summoned to see Aunt Sally F., a lady unusually beloved by all of our community, who, the messenger said, had been "fearfully burned." I at once answered the summons, but did so with the feeling that if the burn was of any magnitude my patient must die, as from previous experience I had learned that the patient had been for years a victim of rheumatic troubles, was at times affected with "rheumatism of the heart," and was also the victim of a large umbilical hernia; also, she had but recently returned from the West (Kansas), where she had suffered from bilious malarial fever, from the effects of which she had not fully recovered. Upon arriving at the house I found the following condition of affairs: The lady's dress had ignited from the fire in the stove, and had literally burned off from her, and upon the body were the following burns, the measurements being in inches: Right arm 6 x 4, left arm 7 x 17, abdomen 9 x 20, right breast 3 x 8, left breast 10 x 4, right hand 2½ x 4, left hand, two places, 2½ x 4 and 2½ x 3; upon the back were five burns, measuring respectively 2 x 2, 6½ x 6, 7¼ x 4½, 2½ x 3½, and 3½ x 5½. These measurements were taken after sloughing had commenced, and were not taken the longest way, but were average measurements. It may be necessary to state that the lady, who is 56 years old, is very large and fleshy

The right arm was burned to the 5th degree (Erichsen), the abdomen to the 3d degree, the rest of the wounds to the 2d degree. The sloughs separated readily. The shock was excessive, but the reaction was not so. The wounds went steadily on toward healing, until, at this date, all are healed, with the exception of an ulcer, the size of a silver dollar, upon the right arm.

The treatment was simple. Oleum lini and aqua calcis until sloughs separated, then cosmoline to the remaining ulcers.

There was no trouble with the heart; no perceptible duodenitis, in fact, no alarming symptoms. The internal treatment consisted of laxatives and occasional diuretics.

The case was seen by my colleague, Dr. A. F. Carr, also by Drs. Leonard French and L. Melville French, of Manchester. I think this case shows us that a strong will on the part of the patient, combined with good nursing, can carry through cases that we are inclined to consider hopeless.

Frank Blaisdell, M.D.

Goffstown, N. H., Dec. 21st, 1880.

On the Propriety of Publishing Medical Lectures.

Ed. Med. and Surg. Reporter:—

According to an argument in the November number of *Gaillard's Medical Journal*, on "Hospital and College Lectures," such works as Watson's Practice, Sayre's Orthopædic Surgery, etc., should be discarded from physicians' libraries. Such works, of course, were lectures, delivered to medical students.

He says:—"As these lectures are intended for medical students, and often for students attending their first course, the publication of them for the instruction of experienced practitioners is inappropriate and incomprehensible."

If this be true, what is the use of "experienced practitioners" attending medical lectures? Medical students are entitled to, and should receive, as thorough teaching as medical practitioners, for the "tree will grow as the twig has been trained," and if the medical student is unable to comprehend thorough teaching he should engage in something else. He says:—"They (practitioners) should have their reward in papers prepared for physicians, and not for beginners in the medical field." The trouble is, our journals contain too many such papers, and not enough clinical experience, which could not be presented in a more reliable and practical form than in the publication of clinical lectures delivered by teachers of great clinical experience.

W. J. Owsley, M.D.

New Maysville, Ind., December, 1880.

A Singular Case of Diabetes.

Ed. Med. and Surg. Reporter:—

I have a patient, twenty-six years old, who drinks about thirteen quarts of water, and discharges about the same quantity of urine, every twenty-four hours. The urine is perfectly odorless and colorless, has a specific gravity 1.003, contains neither sugar nor albumen, and has continued thus for the past ten years. The patient appears hearty and strong, and works at an iron manufactory, and complains of nothing except this excessive desire for drink, which floods through the kidneys as fast as he drinks it. About all the prominent remedies laid down for diabetes have been given him, with no beneficial effects. Inasmuch as the urine contains no sugar, and has not the specific gravity found in diabetes, would some of the readers of the Reporter give their opinion and suggest treatment of this peculiar case?

D. C. Laverty, M.D.

Middletown, Pa., December 20, 1880.

News and Miscellany.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service October 1st, 1880, to December 31st, 1880.

Bailhache, P. H., Surgeon. Detailed as chairman Board of Examiners of candidates for promotion, October 6, 1880. To proceed to Norfolk, Va., as inspector, November 1, 1880. Detailed as president Board of Inquiry, to meet in St. Louis, Mo., November 17, 1880, November 9, 1880. Upon conclusion of duties under orders of November 9th, to proceed to Dubuque, Iowa; LaCrosse and Milwaukee, Wis.; Chicago, Ill.; Detroit, Mich.; and Buffalo, N. Y., as inspector, November 10, 1880.

Miller, T. W., Surgeon. Detailed as member Board of Inquiry, to meet in St. Louis, Mo., November 17, 1880, November 9, 1880.

Purviance, George, Surgeon. Detailed as recorder Board of Inquiry, to meet in St. Louis, Mo., November 17, 1880, November 9, 1880. Upon conclusion of duties under orders of November 9th, to proceed to Louisville, Ky., as inspector, November 19, 1880.

Doering, E. J., Surgeon. Granted leave of absence for thirteen days from January 3, 1881, December 29, 1880.

Smith, Henry, Passed Asst. Surgeon. To proceed to Key West, Fla., and assume temporary charge of the Service at that port, December 13, 1880.

Fisher, J. C., Passed Asst. Surgeon. Detailed as recorder Board of Examiners of candidates for promotion, October 6, 1880.

Keyes, H. M., Asst. Surgeon. To report to president Board of Inquiry, November 17, 1880, November 10, 1880.

Cooke, H. P., Asst. Surgeon. To proceed to Galveston, Texas, and assume charge of the Service at that port, relieving Assistant Surgeon Guitéras, December 14, 1880.

Heath, W. H., Asst. Surgeon. Granted leave of absence for twenty days, from Oct. 21, 1880, Oct. 20, 1880. To proceed to Buffalo, N. Y., and assume temporary charge of the service at that port, relieving Assistant Surgeon Cooke, Nov. 18, 1880. To assume charge of the Service at Buffalo, Dec. 14, 1880.

Guitéras, John, Asst. Surgeon. To proceed to Galveston, Texas, and assume temporary charge of the Service at that port, relieving Passed Assistant Surgeon Smith, Dec. 13, 1880. When relieved by Assistant Surgeon Cooke to rejoin his station, Dec 15, 1880.

Wheeler, W. A., Asst. Surgeon. To proceed to Pittsburgh, Pa., and report for temporary duty to Surgeon Purviance, Nov. 10, 1880. Relieved from further duty at Pittsburgh, and ordered to report to Surgeon Fessenden at New York, Nov. 27, 1880.

Benson, J. A., Asst. Surgeon. To proceed to Boston, Mass., and report for temporary duty to Surgeon Vansant, Oct. 15, 1880.

Banks, C. E., Asst. Surgeon. To act as inspector of unserviceable hospital property at San Francisco, Cal., Nov. 2, 1880.

RESIGNATION.

Brown, F. H., Passed Asst. Surgeon. Resignation accepted by the Secretary of the Treasury, to take effect Nov. 5, 1880, Oct. 7, 1880.

PROMOTION.

Goldsborough, C. B., Passed Asst. Surgeon. Promoted to be Passed Asst. Surgeon from Oct. 14, 1880, Oct. 14, 1880.

DEATH.

Glazier, W. C. W., Asst. Surgeon. Died at Key West, Fla., of yellow fever, Dec. 12, 1880.

DISMISSED.

Keyes, H. M., Asst. Surgeon. Dismissed the Service, to take effect Dec. 31, 1880, Dec. 24, 1880.

—A choleriform disease has prevailed with considerable severity in one of the hotels of Little Rock, Arkansas. The Board of Health has taken no action, and the local newspapers have kept very silent about it.

The Bogus Diploma Business in Pennsylvania.

The Governor of this State, in his annual message, given to the public last week, presents a succinct resumé of what was done by the authorities to check the disgraceful traffic in diplomas in this Commonwealth. He states that the General Assembly requested the Attorney General to institute proceedings in the Courts against the American University of Philadelphia, on account of the abuse of its franchises "in the unlawful sale of diplomas to persons who had not pursued the prescribed course of study, and who were unfitted, by reason of ignorance, to practice medicine." In accordance with this request writs of quo warranto were sued out by him against the American University of Philadelphia and the Eclectic Medical College of Pennsylvania, another institution claiming a like charter, and managed by the same persons controlling the American University. In both cases favorable judgments have been rendered, and the said charters declared forfeited by the Courts, and as an incidental result, the manager and official head of these institutions has been convicted and imprisoned for violating the laws relative to the sale of diplomas and other crimes. Proceedings, not yet terminated, have also been commenced against the Philadelphia University of Medicine and Surgery.

This action on the part of the State authorities has not been too speedy. Evidence of the sale of diplomas in large numbers, not only in this country but in England and on the Continent of Europe, has been secured, and complaints transmitted through our representatives abroad to the State Department at Washington, of the presence in the hands of grossly ignorant persons of regularly issued diplomas from institutions chartered by the State of Pennsylvania, authorizing the holders to practice medicine, are corroborative of ascertained facts. It was high time that so serious a disgrace to the good name of the State should be abated.

No appropriation was made to enable the Attorney General to prosecute this work, and he was practically powerless until the necessary means were advanced by a public-spirited citizen of Philadelphia, to whom, it is hoped, recompense will be speedily made, through appropriate legislation. The Governor recommends the adoption of a system of registration of medical diplomas, with appropriate penalties for non-registration or for practicing under a diploma irregularly obtained.

The Adulteration of Drugs.

According to a report on this subject to the National Board of Health, by C. Lewis Diehl, it is gratifying to know that persons who really desire to obtain articles of standard quality, and at a proportionate price, have very little difficulty in being able to do so, and can be suited by respectable dealers throughout the land, while poor and adulterated articles are present, and are very likely to be obtained by ignorant persons or by those who are indifferent to the character of the dealer, and are desirous of regulating their purchases by the price rather than the quality of the goods. Crude drugs can usually be obtained of good quality, though many are sold which have deteriorated by prolonged or careless preservation. Powdered drugs (those of fair quality can usually be obtained) are liable to the grossest adulterations, particularly those which are frequently handled (like spices) by both grocers and druggists. That this practice still continues is shown by the fact that powders are often sold at the price of, or at an inadequate advance upon, the crude drug, notwithstanding the loss incurred in drying and powdering. Infusions, decoctions, solid and fluid extracts and tinctures are all found to vary in strength and quality, from good and indifferent to positively bad; some manufacturers adhering to the requirements of the Pharmacopœia, while others admit inferiorities in order to save cost and to be able to undersell.

The International Sanitary Conference.

The conference held its first meeting January 5th. Mr. John H. Hay, Assistant Secretary of State, was appointed chairman, but owing to the delay in the arrival of several foreign delegates, an adjournment was made to January 12th. One of the leading members stated that the principal object which the Boards of Health hope to accomplish through the medium of the Conference is to obtain the right to search all vessels which may arrive or leave ports of the United States, to ascertain the presence of disease on board. There have been three or four international sanitary conferences during the past twenty years, the chief object of which has been to secure some international quarantine regulations. All attempts to accomplish this end have failed, and the Board has abandoned all hopes of trying to secure international quarantine. The bill which created the National Board of Health gave that body the right to search vessels to ascertain the presence of disease, but, of course, the power was nugatory under the present international understanding on that subject.

The Condition of Malaga.

Malaga has some repute as a health resort. But, as with most Mediterranean cities, it has some unpleasant features. United States Consul H. C. Marston gives the following in regard to the sanitary condition of the city. In the old portion of Malaga the streets are exceedingly narrow, some of them not exceeding fifteen feet in width, and only on certain streets can a conveyance of any kind be driven. These narrow streets are paved with large boulders, and are kept tolerably free from dirt, but the drainage from the dwellings is very bad, and in almost every house the smell from the drain, together with the smell of a very inferior quality of oil used by the lower classes in cooking, is beyond description. The fact that Malaga escapes an epidemic can only be attributed to the excellence of the climate.

—An International Anti-vaccination Congress was held not long since at Paris.

New York State Insane Asylums.

The efforts of Drs. Seguin, Hammond, Spitzka and others have led to a pretty thorough airing of the condition of the insane in New York State. A Senate Committee spent some time, last month, in taking testimony and making personal inspections. Considerable crookedness was developed, such as appointments and removals by political and personal influence, the too free use of cribs and camisoles, incompetence of assistants, etc. The report of the Committee will probably largely justify the severe censures which a year ago were made by the gentlemen we have named, on the treatment of the insane in the New York hospitals and asylums.

Centenarians.

—Mrs. Harriet N. Cooper, a colored woman, died at Cheltenham, near St. Louis, on New Year's day, aged 115 years. She weighed 400 pounds. Mrs. Cooper was the mother of twenty-five children, the youngest of whom is 62 years old. Her husband is 101 years of age and is still living.

—Miss Betsy Rooth, of Greenville, Conn., who died last week, aged 100 years and 4 months, was the oldest person in Eastern Connecticut.

Florida this Winter.

A private letter from Jacksonville, dated Dec. 30th, informs us that on that day the thermometer fell 50° in ten hours, and was then as low as 18°. Ice was two inches thick. There has been a great deal of malarial fever in that State the past fall and early winter, and the prospects for an active "season" are not excessively bright.

Personal.

—Dr. Albert W. Murphy, a genuine live Yankee from New Hampshire, has been appointed dentist to the Royal Court of Spain, with a residence at Madrid.

—Dr. John Stenhouse, F. R. S., the very distinguished Scottish chemist and sanitarian, is dead, aged 71 years. He was born in Glasgow, October 21st, 1809, and was educated at Glasgow Grammar School, at Anderson College and the University of Glasgow, where he studied chemisty under Professors Graham and Thomson. Dr. Stenhouse was the author of nearly one hundred papers on chemical subjects specially devoted to sanitary purposes.

—Dr. H. W. Gedicke of Newark, N. J., was sentenced, last week, to ten years in the State Prison and to pay a fine of $2000, for an attempt to procure an abortion. The severity of the sentence caused considerable surprise, as the abortion was not performed, and there was some evidence that looked as if the charge was an effort at blackmail.

—Dr. Wm. S. Janney assumed the duties of Coroner of Philadelphia last week. He appointed as Chemical Analyst, Dr. John J. Reese, and as Physicians, Drs. Joseph Neff and John G. Lee.

The International Congress of Hygiene.

It is announced officially, that the fourth International Congress of Hygiene will be held at Geneva in September, 1882, and it is confidently anticipated that London will have the honor of entertaining the fifth Congress in 1884. At Turin, where it was held last summer, as at Paris, the number of English and American members present was very small indeed, and they contributed little to the scientific work done.

Items

—The smallpox in Philadelphia continues to demand from thirty to forty victims per week.

—In New York and Brooklyn the epidemic of diphtheria seems to abate but little, the mortality continuing to be large. About one death an hour took place from this disease in New York last week.

—The French Society of Hygiene passed a resolution at its last sitting, that it was desirable that a canal be constructed from Paris to the sea, in order to discharge on the coast the contents of the sewers, and that this should also receive the offal and night soil of the capital.

OBITUARY NOTICE.

Dr. E. M. Wight, aged 40, died of pneumonia, at Chattanooga, Tennessee, January 6th. He was a member of the Tennessee State Board of Health, Inspector of the National Board of Health in 1879, and enjoyed a wide reputation in the South as a physician and politician. He was the Republican candidate for Governor in 1878, and for two terms was Mayor of Chattanooga.

QUERIES AND REPLIES.

Dr. L. P., of N.Y.—We can subscribe for you to any French medical journal you wish. *Le Progres Médical*, or the *Gazette des Hôpitaux* are about the best.

Student.—The word "Cornage" is not to be found in the medical dictionaries. It was introduced, we believe, by Professor Sée, of Paris, and is a harsh, noisy respiration, pathognomonic of stricture in the air ducts.

Dr. J. S. K., of Pa.—Boracic acid has been tried in diphtheria. Dr. Jacobi speaks unfavorably of it. Others have claimed good effects.

Dr. Alphonso.—1st. Goitre is not rare in the lower animals. The dogs of Salzburg often have it. 2d. We doubt if the exciting cause of goitre is clearly made out.

MR. EDITOR:—In "A Tough Case," by Dr Fierce, in REPORTER, January 1st, 1881, use general and local faradization (with Horsford's Liquid Acid Phosphates internally), twice or thrice a week.

Tennessee. S. W. CALDWELL, M.D.

MARRIAGES.

YOUNG—STARKS.—At the Methodist Church, in Como, Mississippi, December 28th, 1880, by Rev. C. N. Terry, A. A. Young, M.D., and Mary C. Starks, daughter of the late Rev. S. G. Starks.

CLOUD-SHARPE.—At Savannah, Ga., Dr. J. A. Cloud and Mrs. A. A. Sharpe, of Boston, daughter of Hon. John Hickman, of Pennsylvania.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price. QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

Lecture.

SYPHILIS IN MARRIED LIFE.

Delivered at the St. Louis Hospital (Paris), by M. Fournier, Professor of Skin Diseases, of the Paris Faculty of Medicine.

(*Translated for the* Med. and Surg. Reporter.)

Gentlemen—How often, in your practice, are you consulted by individuals with whom you are or are not acquainted, who commence by saying that a favorable occasion of marriage presents itself to them, but that, having been unfortunate enough to contract syphilis a few years previously, they desire to know if they are completely cured, and if they may marry with safety!

The importance of the reply you will make to such a question cannot be over-rated; you assume considerable responsibility, for there are few problems in medicine so difficult of solution and of so much gravity.

If, on the one hand, you interdict marriage to a man in fit condition to marry, you eject without the pale of regular existence a man who desires to enter; your medical sentence may destroy his happiness and his subsequent career. While, on the other hand, if you authorize the marriage of a man still suffering from syphilis, you expose not only the individual himself, but also his young wife, to whom he brings the disease as a wedding present, and again the entire family which may result from the union.

I have witnessed too often these sad dramas of family life, and I can affirm to you that nothing can be more execrable than the situation of such a man before a wife who weeps, but forgives; before her family who do not forgive, and before a nurse, infected by the child, who recriminates, gives rise to scandal, and divulges the secret. We will, then, seek to resolve this terrible problem regarding syphilis in the marriage relations. And, primarily, an important question presents itself for consideration.

Does syphilis constitute an absolute obstacle to marriage? "A man who has the syphilis should remain a bachelor;" this is what you will very often hear said in public, and sometimes even by physicians. I could cite two very honorable practitioners of my acquaintance who, joining practice with precept, have renounced marriage on this account. One of the two, who enjoys a high reputation, has never allowed himself to be persuaded by me, and always replies: "When a person has syphilis, he should keep it for himself alone."

To this profession of faith, dictated by sentiments of delicacy in a highly honorable man, I reply: when one has the syphilis it should be cured, and then marriage and a family may be thought of.

Syphilis is not an insurmountable obstacle to, nor an absolute interdiction of, marriage; daily observation shows cases where such marriages have been contracted with safety; we meet every day with married men whom we have seen suffering from syphilitic lesions, and who have transmitted absolutely nothing to their wives, and have children as healthy and flourishing as they can desire. The proofs of the truth of this assertion abound; I defy any physician who has practiced several years to affirm that he has not observed such cases.

I have been able to find fifty-one published cases besides those I have observed in my own

practice. These fifty-one syphilitic fathers had ninety-two children, all free from the disease. I recall one such case where there were four children, and another where five children were born. I have been physician of both families for many years, and have never observed a trace of syphilis in the children. I conclude, then, by asserting, with a conviction fortified by observation, yes, a hundred times yes, a man may enter the married state after having contracted syphilis; but he should marry only under certain conditions, which it is now necessary to determine.

What are the dangers which a syphilitic subject brings into the married state?

A man who marries while still suffering from syphilis is dangerous as a husband, as a father, as head of a family.

I. He is dangerous as a husband, by the lesions to which he exposes his wife, and in two ways:—

1st. By simple, common, vulgar contagion, through which he may transmit syphilitic lesions in the thousand intimate relations of married life. To cite but one instance: a young man of excellent family, who married, notwithstanding my advice to the contrary, had syphilitic ulcerations of the lips, combined with others produced by cigarette smoking; three months after his marriage his wife had an indurated labial chancre, the result of a syphilis which is not yet cured.

Cases of this kind are very frequent among young married couples, and are easily explained, for secondary lesions are extremely contagious, and the familiar relations of domestic life involve close and constant personal contact. It would be a rare exception to see a young wife live many months with a syphilitic husband without contracting the disease; as a witty author has said, syphilis is shared among married people as is their daily bread.

2d. By placental contagion, or by conception. A young girl espouses a man presenting syphilitic lesions; after being married a few months a physician is called to the young wife, who presents strange and uncommon symptoms; syphilitic eruptions are found, mucous patches about the mouth, glandular enlargements, falling of the hair (alopecia), etc. If the physician seeks for the origin of these lesions, he is unable to find any trace of initial chancre, or of a bubo, faithful companion of the chancre; secondary lesions alone are found, without any trace of primary lesion; on the other hand, if the husband is questioned in secret, he will affirm and protest energetically, that he has never had any venereal disease, that he has always carefully examined himself after intercourse, etc.

He is right; in effect his wife may become syphilitic through contact with this man who exteriorly appears not to suffer from the disease; this apparently paradoxical fact has been too frequently observed to place its occurrence for one instant in doubt. This mysterious contagion is explained by the fact that the woman is with child. Always, in such cases, you will find that the woman has borne a child or had a miscarriage a short time previously. The mother has, in fact, been infected by the child and not by the father. Contagion has taken place through the placental exchange going on between mother and child; a fact absolutely proven to-day.

To resume: A syphilitic husband may become dangerous for his wife: 1st. Directly, by transmission of syphilitic lesions. 2d. Indirectly, through his fecundating power, by procreating a syphilitic child, which infects its mother.

II. A man still suffering from syphilis is dangerous as a father for his children. Up to a very recent period, hereditary transmission of syphilis was accepted as a proven fact, but the aspect of the question is no longer the same: in Germany, notably, there has been a desire evinced to restrict the paternal influence in such transmission. For certain authors the syphilis of the father rarely becomes hereditary; for others it is never so; it has even been said that the paternal influence at this point of view is nil, amounts to nothing, and that the child of a syphilitic father is healthy.

This doctrine is burdened with exaggeration, with enormous errors, which, in order to afford protection for society, if for no other reason, should be combated energetically. I hold it as a constant fact that a syphilitic father is dangerous for his children.

But I admit that the possibility of transmission is much less certain than has been generally supposed when the father alone is affected, the mother remaining free from the disease.

When the father is syphilitic and the mother is not infected, the child has every chance, *if brought into the world*, of not being syphilitic.

These concessions made to the partisans of the doctrine I combat, I proclaim the results of observation, and deny the truth of the assertion that the influence of the father is never manifest in the fœtus.

Paternal influence may be rare and restricted, but it is sometimes exercised.

Syphilitic fathers have procreated syphilitic

children, the mother remaining free from infection; Ricord, Trousseau, Diday, Liégeois, have all given incontestable cases. But this is but a part of the question, which assumes gravity from the following considerations: The death of the fœtus in utero is very frequent under the conditions of which we speak. The child of a syphilitic father dies in the womb of its mother and is expelled by miscarriage or by premature labor.

A young wife becoming enceinte has one, two, three miscarriages, without it being possible to find any other cause except the syphilis of the father.

And what proves this to be the real cause? if the father places himself under a course of treatment the following pregnancies proceed to full term and the children are born alive, without the disease.

I have observed such cases very many times. I will cite one case among many others: One day I met a former companion, whom I had not seen for a long period. He recounted to me his history and his troubles. His wife, though of fine constitution and very strong, had miscarried four times in succession. I then recalled to mind that my friend had suffered, long before, from syphilis, and had not followed any regular course of treatment. I, therefore, advised him to place himself under a course of treatment for his syphilitic affection, which I did not consider cured.

Although my counsel was given in the open air, and on the boulevard, it was rigorously followed, and fifteen months later I learned of the birth of a fine child, who is ten years of age today, and enjoys excellent health. Two ulterior pregnancies in the same case also terminated happily.

To resume: whenever the physician finds himself in the presence of a series of miscarriages, occurring in a healthy woman of good constitution, he should commence to suspect that these accidents are due solely to the syphilis of the father, who has destroyed his child in the womb of its mother.

Another important point is: a syphilitic father is dangerous for his children, as the spouse of their mother; in effect, he may transmit the disease to his wife, and then, the father and mother being syphilitic, what will be the condition of the children?

Three alternatives present themselves:—

1. The child will perish in utero, and that is assuredly the best for the child.

2. He will be born at term, but infected with the disease.

3. He will survive, with his health compromised and exposed to all the alternatives of disease.

a. For the first case—death in utero—experience has demonstrated its frequency; thousands of cases sufficiently prove its occurrence; all the observations are so exactly in concord that they appear stereotyped. The pernicious influence continues to be felt even in ulterior pregnancies; there has been observed series of four, six and seven successive pregnancies terminating always the same way, in miscarriage. I have seen, at the Lourcine Hospital, a young woman, strong and of splendid constitution, who married in her nineteenth year, and had three successful pregnancies. Her husband, in an extra-conjugal adventure, contracted syphilis, communicated it to his wife, who became enceinte and miscarried in the fifth month; a second pregnancy terminated in premature labor, the child being dead; a third, a fourth, a fifth pregnancy had the same ending; the sixth terminated in miscarriage, in the third month; the seventh, at the sixth week, in the same way. This case is extremely interesting—seven miscarriages succeeding three successful pregnancies and supervening after transmission of the disease.

b. In another series of cases the child is born living, but infected with the disease, and is consequently exposed to all the dangers of infantile syphilis, from which, by careful nursing and attention, a few infants may be saved, but the great majority perish.

c. It is possible that the child escape death and the disease also, but the influence of the hereditary taint will show itself in another way; by the natural debility which characterizes the most of these children, who are weakly, wrinkled, like old men, and of very poor constitution; nothing attests the existence of syphilis, but they are so puny that they cannot survive and usually succumb, wasting away gradually, without any apparent disease, no particular lesions being found at the autopsy.

Or, again, they have certain morbid predispositions: 1st. They are born hydrocephalic, or frequently become so. 2d. They are very frequently subject to nervous troubles, to epilepsy, while they are very young, and later to convulsions; they very often die in simple convulsions. Finally, they are generally lymphatic and have feeble vital resistance to scrofula. But scrofula is not, on this account, a metamorphosis of syphilis, as has been erroneously pretended; it is a fixed morbid entity, just as is syphilis; it is, however, incontestable, that venereal disease

constitutes a predisposition to scrofula, inasmuch as it is a debilitating, asthenic malady, acting on the organism in the same deleterious manner as insufficient nourishment, confined, impure air, and crowding in small, humid tenements.

III. A man who marries while still suffering from syphilis is dangerous as head of a family, by reason of the lesions to which he personally is exposed.

This is the most difficult and delicate aspect of the question, not only from a medical standpoint, but also as regards morality and the general principles professed by all honorable men.

The man who has contracted syphilis is exposed to a series of lesions of exceeding gravity, and which often prove fatal. Or, with very rare exceptions, these lesions supervene at an advanced epoch, in the tertiary period, and thus the disease, contracted in the heedless years of youth, becomes of gravity only at a ripe age, when the individual has become the father of a family.

What a sad situation, from a medical point of view, is that of a man who has every chance of suffering from the assaults of the syphilitic diathesis!

He is diseased for the future; physically vitiated; owing a debt to syphilis which must, one day or another, be acquitted.

Is it, then, honorable, is it in accordance with the common principles of morality, that such a man think of becoming a husband and father? It is assuredly against all principles of morality, and is inadmissible. In effect, marriage is not alone an affair of sentiment, of passion, of convenience or of personal interest; it is also, and to view it in a more practical light, a partnership, freely entered into, to which each partner should bring a sufficient share of good health to accomplish the end which marriage should attain in society.

Or, this man brings into the partnership a constitution already hypothecated, owing a debt to syphilis, an inexorable creditor—a debt which he will one day be required to pay. When he finally becomes so infirm that he is no longer able to work for a livelihood, what will become of his wife and children? I demand again, is it honorable for him to think of wife and children, when he can but leave them widows and orphans? The man, still suffering from syphilis and aware of his condition, who places his signature to a marriage contract, is a villain (misérable).

It is exactly as if two individuals formed a copartnership in any business, and while one of the partners brought his share in solid cash, the other could offer nothing but hypothecated values, which would inevitably suffer depreciation. This last is our syphilitic subject, who, in exchange for the health of his young wife, brings into the partnership a vitiated constitution, menaced with every morbid catastrophe.

And do not depart thinking I have exaggerrated in drawing so sombre a picture; I have but presented to you what I have too often seen, these hidden family dramas which are a veritable social misery. I will cite but a few cases taken at random; here it is one of the most popular actors in one of the great theatres, who having contracted syphilis treated it with supreme indifference. Happily he did not infect his wife and had a healthy child, but he was attacked himself later on by a syphilitic ulceration, which took on a phagedenic form. I was unable to arrest its ravages, and it invaded successively the face, nose, upper lip, soft palate and pharynx, and in the end caused the unhappy being to become an object of horror and disgust to all about him. In another case an artist, a painter, contracted syphilis; the disease was incompletely treated, and he was attacked with an affection of the eyes which finally caused complete loss of vision, and the unfortunate was obliged to apply to the public Board of Charities to save himself from starvation. Another case was that of an unfortunate physician, rendered infirm by paraplegia, of syphilitic origin, and unable to save his wife and two children from poverty. A last case: an individual engaged in manufacturing pursuits marries; with his wife's fortune he founds a large factory and the business prospers; seven years after his marriage syphilitic periostosis brings on cerebral lesions, his intellectual faculties are enfeebled, he compromises his fortune, ruins his business, and dies in a state of dementia, leaving his wife and four children in extreme poverty. I could not finish if I undertook to recount all the sad social calamities I have witnessed. What should be said of the author responsible for all these evils? He is more ignorant than guilty, and it is a duty we owe to society to instruct the public concerning these dangers they ignore.

We should enlighten them, show them the abyss they prepare for themselves in neglecting our advice. We should firmly say to any man who wishes to marry while still suffering from syphilis, that if he has full liberty to do as he pleases while he remains a bachelor, he has not the right, by marrying, to associate others in his personal risks.

Communications.

CASES OF EXOPHTHALMIC GOITRE.

Read before the Iowa Union Medical Society.

BY L. J. ADAIR, M.D.,
Of Anamosa, Iowa.

I saw my first case of exophthalmic goitre in 1872. At that time I was comparatively ignorant of even the three principal symptoms of this disease, and, of course, had more or less trouble in diagnosing my case. Books of reference were scarce in my office then—one text-book, an American author, and it perplexingly silent upon the subject. But at last I succeeded in convincing myself that I really had a case of exophthalmic goitre.

Mrs. B., thirty years of age, mother of three children, youngest two years and six months. Visited her January 17th, 1872. She was suffering at that time with violent attacks of palpitation, with difficulty of breathing, amounting almost to suffocation. Was anæmic; very excitable; respiration thirty or forty per minute; pulse 130; troublesome beating in the head and neck; difficulty of swallowing; voice changed; nausea and vomiting. There was bulging of the chest wall in the region of the heart and extensive dullness over the left side of the chest. She had not menstruated since the birth of her last child. Thyroid slightly enlarged, mostly upon the right side. There was no exophthalmus, but a very peculiar expression of her eyes that I cannot well describe. The attacks of palpitation and difficulty of breathing was what alarmed her most. She had been told by a physician in whom she had a great deal of confidence that she had an affection of the heart that would soon end her earthly career, and, of course, I was often importuned to know if I thought she really had disease of the heart. As I was uncertain as to the true nature of her affection, I evaded any explanation, and comforted her as much as I well could with the assurance that perhaps there was help for her. She stated to me, at a subsequent visit, that the enlargement of her neck was of old date, was first noticed when she was a girl sixteen or seventeen years of age, that she had always had palpitation upon the least excitement, and an occasional attack of suffocation. But not until after her confinement with her last child was her health so much impaired that this poor woman confined herself to her bed, expecting that every attack would be her last. Of course, she was very much alarmed about herself, and I think fright was a great consideration in her case; yet her condition was most pitiable, and I did not envy the physician who had thus, through ignorance, taken away the hope of a return to health and family. So far as the treatment was concerned, I followed this case through many weeks, with variable changes. Tonics—quinia, strychnia and iron, quinia and iron, valerian and iron, alteratives, etc., etc.. My patient was no better; she was discouraged, and so was I.

I often thought of the story I once heard an old practitioner relate some years since, which was, that while practicing in Michigan years ago—the country was new, and economy with him was all important—he would put all the odd bits and parcels of medicine that naturally accumulated about his office into a jug, and add, now and then, a little water to supply the waste by evaporation, etc., and when he had a case that troubled him, and the pay was poor, he would give a dose out of his jug. He said it almost always hit.

At last, I gave my patient tincture digitalis, and how I came to do it I do not remember; I think it was given with iron at first, and finally the iron left out of the prescription, and the digitalis given alone; the object was to lower the heart's action, and to do so, large doses were given, increasing each day, or each alternate day, until the object was attained. She began to improve slowly at first; the attacks of palpitation were less frequent and less severe; her appetite improved; pulse went down to 70 or 80; began to menstruate in two months. Added cimicifuga to digitalis, when the improvement was rapid. Eventually she regained tolerable health. The cardiac dullness disappeared, with fullness also. In 1874 she became pregnant, and miscarried at three months, when she had a slight return of her old disease, but soon recovered. The following year she again became pregnant, and went to full term. While in this condition she had an attack of rheumatism, subacute. While nursing her babe she became very nervous, with palpitation. I advised weaning the child, and she again rallied, and enjoyed very good health. The goitre never disappeared, and never seemed to change very much. In 1878 the family moved away, and I have only learned through her friends that she enjoys fair health.

Case 2.—June 14th, 1876, a young lady of twenty years came to my office, accompanied by her mother, who stated that her daughter had been ailing for three or four months. The first that was observed was that the girl was becoming very irritable in temper, that she did not have her courses, and was growing thin and pale;

appetite was not so good as usual; that she was in good health previous to that time, excepting that she had rheumatism at the age of eleven or twelve.

The first thing that attracted my attention was the unnatural prominence of her eyes, with a peculiar savage expression. I asked to see her neck. Found a large goitre, that seemed very low down, which I attributed to pressure. Examined heart and found violent throbbing, with blowing sound; pulse 130. Learned that she had attacks of palpitation, and sometimes a choking sensation. I also observed choreic movements of hands and arms, especially upon the right side. She also stated that upon several occasions she had fallen, partially unconscious. Suspecting that this last symptom might be owing to uræmic poisoning, I examined her urine. There was a trace of albumen. She was not conscious of the rapid action of her heart, only at the paroxysm of palpitation. She was sleepless; had œdema of lower extremities, anorexia and profuse sweating. I prescribed comp. jalap powder, to be followed with quinia and iron. To report to me again in three or four days. At the end of the fourth day I saw her. She was in about the same condition as when I saw her last. At this visit I put her upon tr. digitalis, increasing, to the effect of lowering the heart's action, which was accomplished in one week. From this time she began to improve; her courses came on in due time, and she made a good recovery. For the goitre I used subcutaneous injection of ergotine, with good effect, materially reducing the goitre. The eyes returned to nearly their natural position, and to all appearance this lady has regained her usual health. She is married and has one child, with no symptoms of a return of the old disease.

On May 4th, 1880, I visited a young lady of 17 or 18 years. She was suffering at the time from an attack of palpitation and dyspnœa; had not menstruated for over a year; was dropsical; thyroid enlarged; eyes protruded; pulse 140. The history of the case was that in March, a year previous, she had been feeling badly; was nervous and excitable, and ceased to menstruate. During the summer months she had an attack of dysentery, which reduced her very greatly, from which she did not recover fully until fall, when the exophthalmus was noticed; also the goitre. She remained very excitable. The heart-beat was rapid and violent. What the treatment was I did not fully learn, only that it probably was sustaining, with an occasional electric bath. During the early spring she was sent away to a neighboring city and given in charge of a homœopathist, whose treatment consisted in the administration of emmenagogues. Not succeeding, he proposed local treatment for a metritis, as he wrote her mother. Not thinking this kind of treatment proper for her daughter, the mother wrote her to come home. She was not improved, excepting that her appetite was better and she was a little stronger.

At the date of my first visit I began the administration of tincture digitalis, in very large doses, with a view of reducing the action of her heart. I succeeded in keeping the pulse about 80 to 100, occasionally below, a few beats. I kept this patient for weeks upon fifteen to thirty-five drops of the tincture. She began to menstruate in two months and continued quite regularly to the present. Her health is quite improved. The exophthalmus is not so noticeable. The thyroid enlargement was not changed until September, when I began the administration of ergot in combination with digitalis and cimicifuga. At present it is much smaller. She has put on flesh rapidly, feels strong, and, I believe, is on the way to a fair, if not a perfect, recovery.

Clara S. came to my office in July; was complaining of palpitation and difficulty of breathing, and felt that she was growing weaker. Her pulse was 120, eyes protruding, thyroid enlarged; there was also œdema of lower extremities. There were choreic movements of right side, cardiac dullness with anæmic murmur, her appetite usually good, does not sleep well. I began treatment with the digitalis, with improvement. I am not able to state whether the cardiac dullness noticed in these cases was due to hypertrophy or dilatation, or both, only I am quite sure that it did exist. Trousseau claims that the dullness is due to exaggerated impulse of the heart and arteries. The recovery in these cases makes me skeptical as to its being either hypertrophy or dilatation. Whatever the true pathological condition is, I certainly believe it curable. A peculiarity in two of these cases was the choreic movements and loss of sensibility upon right side. I can offer no explanation excepting that perhaps it may be confirmatory of the neurotic theory of this strange disease.

In all cases of Grave's disease the heart appears to be primarily affected, and then follows the long train of symptoms, usually the exopthalmus appearing first, and then the thyroid enlargement, after which follow the paroxysm of suffocation from pressure upon the recurrent laryngeal nerve, excessive nervous manifestation, œdema, peculiar cachexy, etc. The cause of this

disease is said to be stimulus applied to the cervical sympathetic; by others to anæmia of the pons, producing a failure of sensibility in the vaso-dilator or regulating nerves of the heart.

Whatever the cause may be, it seems to me a vast field for observation, and American investigation is far behind other countries in this field, at least I am not aware of any particular effort in this direction.

SOUTHWESTERN TEXAS AS A HEALTH RESORT.

BY MRS. GULNARE GARRISON,
Of De Witt, Arkansas.

My husband, Dr. J. B. Garrison, having been requested by the editor of this journal to write an article for publication, on the subject of southwestern Texas as a health resort for consumptives and other invalids, has transferred the duty to myself, thinking that my facilities for doing so were greater than his own, from a personal experience of three successive winters spent in that delightful locality.

In 1870, my husband's mother, then nearly 60 years old and in an advanced stage of consumption, left her home in West Tennessee, and after a few years' sojourn in southwest Texas regained her health entirely, and is now enjoying a degree of health and vigor rarely equaled by persons of her age. Since that time a great many patients, principally consumptive and scrofulous invalids, have been sent to that region by my husband, all of whom have recovered.

In the home of the Doctor's father, Rev. R. C. Garrison, on the bank of a beautiful little river, the Cibolo (pronounced Seewilla), twenty miles southeast of San Antonio, my past three winters have been spent. Twice have I left my home when the very thought of life was a burden; when my friends, at parting, felt that our next meeting would be in a world beyond; but a few weeks in that vivifying atmosphere gave a new life impetus, and now my health is perfect, and I weigh more than ever before; while, anterior to my first visit, I was the subject of repeated hemorrhages from the lungs, with all their attendant horrors. One noticeable feature of my case was, that having been a great sufferer from chronic nasal catarrh, all evidence of the malady ceased within three weeks after my arrival in southwest Texas, and on my return home to Arkansas after the first visit, in about the same length of time all the symptoms returned.

The climate is a variable one; at one hour quiet, summer weather, while the next, perhaps, you are shivering under warm shawls, before a fire, hiding from some fierce "norther." These Arctic blasts last from twelve to thirty-six hours, yet, strange to say, no one ever "takes cold," as is the result of such sudden changes further north.

Invalids seeking homes here must not expect to find them luxurious, for until the last few years most of it was wild land. Now civilization, with its comforts, has kept pace with the tramp of the iron horse, while churches, schools and villages everywhere give evidence of rapid social progress. But health-seekers should want little else.

Sutherland Springs, in Wilson county, is quite a resort for invalids at all times. In addition to its pure atmosphere, the medicinal value of the water of the Springs has proven to be very valuable. They are variously named according to their chemical constituents, Black and White Sulphur, Sour, Iron, etc.

The village is small, but prettily situated near the Cibolo; accommodations tolerably good; board $10 to $20 per month; but few require hotel accessories, and the great desire to be in the open air all the time causes a boarding-house to be anything but a necessity. A village of canvas will spring up, as if by magic, in a night. So pure is the air, and so health-giving the atmosphere, that the veriest invalid, the most delicately-constituted, can "rough it" with impunity in the wild woods, sleep sweetly and securely in a tent, feeling that each day and night so spent gives a new lease of life. I can instance a friend of mine, quite an old lady, who for twenty-five years or more had been a great sufferer from some uterine affection, who, for all these years, had not been able to make her bed, sweep her room, or walk a square—in fact, was almost helpless. She left her Tennessee home, and chance guiding her to this village of springs, she gave them a faithful trial, taking baths and drinking from a peculiar, sour spring, said to belong exclusively to women.

She was two years at this place; her health was renewed, and she went further West. She is now living in a little mountain village, fifty miles west of San Antonio, keeping house and boarders, doing all the work that keeping house, unaided by servants, means, and in perfect health. This cure seems miraculous to those who know her. Her home, the village of Bandera, in a county of same name, is now quite a resort for persons with some varieties of lung trouble.

The safest plan for all patients is to go first to San Antonio, and there consult some physician as to the most suitable locality for their

peculiar malady, or condition. San Antonio is easily reached by rail, and a trip over that line is sufficient in itself to infuse new life into one's veins. Down the St. L. and T. M. R. R. to Texarkana, where you are sure of a good breakfast before entering Texas; then on over the T. M. and Great Southern you pass all day, and each hour see something new and interesting. When night comes you sleep comfortably in luxurious coaches, and awake to breakfast again in Houston. Thence onward, in an elegant drawing room car, you pass over the "Sunset" route, to sleep in San Antonio, the Venice of America.

Each street traversed by canals leading from a silver stream flowing directly through the city, spanned by bridges, rustic and substantial, and marble terraces leading down to the boat houses by the water side, presents a charming picture.

A morning drive from San Pedro park, north, at the head of the river, southward through the city down Garden street, will show the park, charming with its wilderness of wild beauty and its groves of live oaks.

Westward, in the mountains of Bandera, much of interest will be found. The people are generous, genial and prosperous. There is entire safety for life and property, and the inhabitants are intelligent and often refined.

POST-PARTUM HEMORRHAGE AND ITS TREATMENT.

Read before the Tompkins County Medical Society.

BY S. P. SACKETT, M.D.,
Of Ithaca, N. Y.

As I wish to say something of flooding following delivery, I will commence by relating a case that recently occurred in my practice.

October 26th, 1880, I was called to attend Mrs. Eldridge, aged twenty-five, primipara. Her appearance was anæmic, and she said that she had not previously had good health. I delivered her, after a labor of thirty hours' continuance, of a male child weighing nine pounds, using forceps at the last, after I was satisfied that there was inertia of the womb, and that the pains were evidently inefficient.

Before applying the forceps she was laid across the bed, with her feet drawn up on the edge of the bed, and the child and then the afterbirth delivered, without any unusual difficulty or hemorrhage, and from the position and exposure of the parts, I was able to observe just how much blood was lost. Immediately afterward the blood came in a profuse torrent, producing some evident change in her pulse and countenance, which showed some signs of approaching collapse.

My hand had been placed on the abdomen, to make pressure while I removed the placenta, and I again placed my left hand on the bowels and endeavored to grasp the uterus, while I passed my right hand into the vagina to reach the womb, to stimulate it to contract, by friction on the inside. At first I removed two clots as large as my fist from the vagina and womb, and then, as two or three more immediately formed, I removed them, also, and then soon ceased to irritate the womb, and held my hand quite still in the vagina. Within about one minute the flooding ceased, and after holding my hand still one minute longer, I removed it, and also the new clots that had formed, and the patient did not suffer from any unusual hemorrhage afterward. She had a tolerably good recovery, though she remained for some time weak and anæmic.

Without commenting on this case further than to say that, in a similar case I should try the plan again of using my hand as a tampon, I will proceed to give my views of the treatment of post partum hemorrhage.

In order to be prepared for an emergency, the practitioner of obstetrics should in each case be armed with ergot, opium, veratrum, some diffusible stimulant, such as aromatic ammonia, aromatic powder or brandy, one of the persalts of iron, tinct. iodine, carbolic acid, permanganate of potash and alum, or aluminate of iron, glycerine, ergotine and acetate of lead. He should also, without parade, see that hot and cold water are near at hand, and, as I think, also vinegar, and a syringe suitable for vaginal and one for hypodermic use, and ice or snow, if obtainable. I have made a long list of articles, because I can think of some contingencies in which I might desire either of them.

Either opium or ergot may be safely and properly given a short time before the termination of labor, as a precaution to prevent hemorrhage. I may say also that I tie the cord in only one place (instead of two and cutting it between the ligatures), and I am confident that I have less trouble (from either adherent placenta or hemorrhage) thereby. The practice, also, of assisting the expulsion of the placenta by pressure and friction on the abdomen while inducing contraction of the uterus, lessens the liability to flooding.

If troublesome hemorrhage does come on, I should not depend, for even a minute, entirely upon such manipulations with my hands as I have indicated. While doing what I could myself, I should direct a nurse or assistant to ligate the thigh tightly with a cord, a practice that has been

effective in other hemorrhages, and might be in this.

Subsequent treatment should, of course, vary with the symptoms. If there is faintness or great prostration, I would give an ounce of brandy with nutmeg, believing that it would equalize the circulation and lessen the flow, although I do not permit my patients to take alcoholic stimulants during labor, lest it should cause flooding. Should the pulse be full or hard, we should administer the following remedies successively or alternately if required: Ergot, opium, veratrum, and large doses of acetate of lead.

Without waiting for the effect of internal remedies, I would apply a piece of ice or a cloth wet in cold water to the abdomen, and perhaps press a piece of ice into the vagina.

We should not continue to use the cold applications more than half an hour if they are ineffi cient, and if we do not have ice or snow at hand we may apply a cloth quite hot immediately to the abdomen. At the same time, I would introduce a cloth saturated with vinegar into the uterus, and after squeezing it so as to leave the vinegar there, I would remove the cloth as far down as the vagina. Should hemorrhage still continue, use the following successively as injections into the vagina and womb: 1st. Hot water, of the temperature of 110° to 120°. 2d. A solution of permanganate of potash. 3d. A solution of glycerine and carbolic acid. 4th. A weak solution of iodine. 5th. A solution of some of the salts of iron, of which I prefer Monsel's solution.

I would be willing to substitute alum for either of the above drugs if that was at hand and the others were not. Ergotin may be substituted for ergot, and may be administered hypodermic ally.

In conclusion, I would say that a pulse of 100 or more, after delivery, indicates danger of hemorrhage, and the patient should be watched.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

CLINIC BY PROF. J. M. DA COSTA.

Held December 4th, 1880.

Autopsy of a Case of Typhoid Fever Complicated with Pneumonia and Intestinal Hemorrhage.—Remarks on Intestinal Hemorrhage and its Treatment.

Gentlemen:—I am sorry to say that one of our typhoid fever cases has proved fatal. You will remember the patient recently before you, Michael D., who had the persistent high temperature, which attained 106°, and remained in the neighborhood of 103° and 104°, with only slight remissions and exacerbations, since the date of his admission on November 8th, up to within the last few days; this man died on the 28th, from exhaustion. You will recall the case more readily, from the fact that he had an attack of pneumonia, to which I called your attention when he was before you, as I then told you it was a pneumonia of peculiar character—the pneumonia of typhoid fever. I also discussed his treatment to some extent with you. Cold baths were given, notwithstanding the pulmonary complication, to reduce the temperature, and this expedient proved successful, at least in keeping the temperature from becoming excessive. When it attained 104°, and was rising, he was put at once in a wet-pack, and kept there until it fell two or three degrees; this was applied as the thermometer indicated, even being repeated three times in one night, and once or twice the plunge bath was resorted to (temperature 60°), with marked benefit. A decided peculiarity in this case, which we noticed toward its close, was the tendency for a rise in the temperature early in the morning, for which antipyretic doses of quinine between the hours of four and five o'clock A.M. were administered. We treated the pulmonary complication with turpentine internally and externally; also with stimulants, and at times with ammonia, but that was a passing treatment. On the whole, the quinine and turpentine treatment with counter irritation, with cold baths, was the treatment pursued.

This man, occupying bed No. 7, was a desperately ill man. The disease fluctuated from day to day, but while we always held the prognosis as doubtful, from the very continuation of the case we thought that, after all, recovery might occur; when, unfortunately, a profuse and exhausting intestinal hemorrhage took place. This was met by the administration of ergot internally, and by the use of hypodermic injections of whisky, to which we added a little ammonia, five drops of aqua ammonia to a syringeful of whisky (thirty minims). This revived him, and, indeed, notwithstanding two profuse hemorrhages, and a slighter subsequent one; nothwithstanding, therefore, this profuse bleeding, the hypodermic injections and the ergot seemed to control the grave phenomena. But the loss of blood was too much for him. Struggling as he had been for weeks with this pulmonary complication in addition to the prostration of a low fever, it was impossible for him to react. The bad condition of the blood, moreover, was shown from the livid and ecchymotic spots caused by the hypodermic injections, which afterward formed large bullæ filled with bloody serum. Therefore, this was not so much a death from the typhoid fever, as from an accident in the course of the fever, the intestinal hemorrhage, which may happen in any case of typhoid, let it be light or let it be grave.

I show you here the specimens, which are particularly interesting from the point of view which we took when you saw him, concerning the pathological anatomy of the pulmonary complication of typhoid fever, and partly from the point of view of being a fatal case of intestinal hemorrhage occurring late in the disease.

First, let us look at the lungs. There they are

—the so-called pneumonia of typhoid fever. Now, you perceive, when we examine this lung, that the first thing to note is that there is increased pigmentary deposit, but, with some rare spots excepted, you do not find that the lung tissue is consolidated. At the lower part of both lungs a small portion taken out will sink in water, but all this mass which appears to you to be completely consolidated is still capable of floating. This confirms what I told you about the pneumonia of typhoid fever. It is not a true consolidation. Here and there are spots of consolidation, some groups of collapsing air cells filled with granular material, but without true exudation of lymph, but all the other portions are densely congested. At the base of the right lung, it is true, there is a spot which looks like true pneumonia consolidation, but it is limited; the left lung is more crepitant. Here then is the pneumonia of typhoid; deep congestion, collapse of air cells, with only partial consolidation; both lungs present the same features, only differing in degree.

I will only add, to make the case complete, that there was subsequently no material difference in the physical signs from what you saw when he was before you. There was on one occasion a passing friction, but nothing having any special bearing upon the case.

Here is the typical spleen of typhoid fever. Look at it! Larger and softer than normal, not red, but certainly increased. This is the kind of spleen that you will find in severe cases of typhoid fever. The liver is pale, large and somewhat fatty. I do not consider this as belonging to the disease proper; more likely it is due to previous changes. I do not know what his habits were, but this fatty degeneration does not belong to the typhoid fever process. Now, we will examine the intestines. I want to show you the ulcerating Peyer's patches, from one or two of which the fatal hemorrhage took place. In two places the ulcerations had extended through to the peritoneal coat, though no perforation had taken place. The ulcers were not large, only of medium size, and show in some parts, very evidently, signs of cicatrization. You see here, most distinctly shown, the enlarged solitary glands; though they do not appear ulcerated, they simply seem to be the seat of the typhoid fever deposit. Whereas, in the lower part of the ileum, at this point, you can see the remains of a Peyer's patch, a portion of which has sloughed out; the upper part is still the seat of infiltration; in the lower portion of its extent the process of cicatrization has commenced; the membrane is thin; it is only here, where the surface is depressed, that this ulcer is unhealed. Here is another patch, infiltrated, and the seat of superficial ulceration. Here is one very well marked; the whole patch is prominent, remarkably preserving its shape, and shows beginning abrasion, not deep ulceration.

Now, gentlemen, suffice it to say, that it was from one or two points—we need spend no further time in searching for them among the many spots of ulceration—from which the mucous membrane is entirely gone that these hemorrhages took place. Here is a very large, thoroughly characteristic Peyer's patch, enormous infiltration. Here is what I was telling you about, where there has been almost a perforation; you see this hole which has gone down to the peritoneal surface. A little more, and this would have led to perforation. It is very probable that from this identical patch, or some other just like it, the fatal hemorrhage began.

While, of course, glad of the opportunity to show you these specimens, I am sorry, from the therapeutic point of view, to have this opportunity, and repeat that I do not think that I would have had it but for the hemorrhage which unfortunately occurred.

As you have seen this case before, I will now make some remarks upon the subject of intestinal hemorrhage in typhoid fever and its treatment.

It is a remarkable fact, and one which only illustrates the different character which different epidemics assume, with regard to this complication, that out of all the cases that we have recently had under treatment—and I do not remember in all my experience as physician to this hospital, at any one time, having had so many cases of typhoid fever together in the ward—it is very strange, I say, that this is the first case of intestinal complication that has occurred. Out of this series of cases we have been studying, not one presented a symptom of the kind; out of all the cases I have shown to you, I have not had a single remark to make or a single suggestion to offer as regards the gastro-intestinal complications. This is the first case of intestinal hemorrhage. You have further satisfied yourselves that this hemorrhage came from several unhealed ulcers in the small intestines, which were still progressing, and which would in all probability have led one, at least, to a perforation and fatal peritonitis.

Was this the only cause of the profuse bleeding? Does it always happen from the extensive ulceration, which you see here, that the intestinal hemorrhage occurs, or is there another element present which was largely active in producing this result. Gentlemen, the intestinal hemorrhage is not necessarily linked to extensive and progressive ulceration of the bowels. Generally, when you have marked intestinal hemorrhage, there is another element which determines the bleeding, which is as potent in producing the result as the intestinal lesion; that element is the progressive deterioration of the blood by the prolonged fever process. The hemorrhage is due partly to the ulcerative process and partly to alteration in the blood. Even in extensive ulceration, there may be only small and insignificant amounts of blood in the stools; nothing like a marked hemorrhage. But in other cases of typhoid, hemorrhage of serious character may accompany only slight destruction of glandular patches in the intestine. That is one point: the cause of the hemorrhage is partly local, partly general.

Was there anything in the symptoms which predicted the occurrence of this grave, and as it proved, fatal complication? Could we have foretold it? Did we suspect it? Yes, gentlemen, there was something most significant that took place, which pointed to what was going to happen. You know that this case, throughout, has

been marked by unusual height of temperature; this I have discussed with you, marking 106° on one occasion; 105°, you see, was often attained, indeed, it was rarely under 104° or 103° (except when temporarily under the influence of the bath, or of large doses of quinine). Well, the temperature continued elevated until on the morning of the 25th it fell without obvious cause. We find indicated in the temperature chart a sudden drop in the temperature, from 104° to 101°. This is most significant. That night the hemorrhage occurred. When you have at the height of a case of typhoid fever, which hitherto has been marked by elevation of temperature, such a marked fall as this is, you will be right, in ninety-nine cases out of a hundred, in attributing that fact to intestinal hemorrhage which is taking place, or is about taking place. That is one diagnostic point that I wished to speak of; another point is this: The signs of internal hemorrhage, of course, are the appearance of blood in the stools, and evidently impending collapse. He was perceptibly weaker. Perhaps it was the shock of the hemorrhage which weakened him; but, whether due to remedies employed, or to reaction, he grew better under the use of ergot and stimulants, and we hoped that he would be able to weather the storm, but the hemorrhages (one about a pint, the last about half as much) had been too great, and he died, exhausted, in the course of thirty-six hours after the first hemorrhage.

Now for the treatment. I call your attention to the treatment pursued. Ergot by the mouth, some stimulants, to revive him, of course, but ergot by the mouth and hypodermic injections of whisky, with a little ammonia, constituted the main reliance. I should have liked to have given the ergot hypodermically, and under other circumstances would have done so, for I believe that ergot is the best agent in the treatment of intestinal hemorrhage of typhoid fever, and that hypodermic injection is the best method of giving it. Why did we not employ it here? Because the few injections of whisky and ammonia were followed by so much extravasation about the point of puncture, that the idea of administering ergot by this route was at once abandoned. We gave twenty minims every three hours, by the mouth; and after he came fully under its influence there was no more hemorrhage.

What about the hypodermic injection of stimulants? I have often resorted to the injection of whisky and ammonia in temporary conditions (3 to 5 drops aqua ammonia, whisky 30 minims), with marked benefit. It is a powerful stimulant to the circulation, enabling us to rapidly produce an effect, and, in emergencies, may save life, or at least revive the patient and gain time, so that other remedies may have an opportunity of producing their effect.

Pneumonia Occurring in an Emphysematous Lung. Remarks upon the Peculiar Physical Signs.

Upon the discussion of this case I shall not spend much time. He came in with a history of remittent fever; of this there is no doubt, and when we saw him he was in the third week, or at least the second week was completed. There was some little uncertainty about its duration, but none as to its character, for, from his general condition, and the size of the spleen, there could be no doubt that he had passed through an attack of malarial fever. Shortly after he came into the hospital—indeed, at the first examination—we detected dullness at the base of the right lung, with some râles, enfeebled breathing, but without marked tubular breathing. We recognized that we had to deal with an acute pulmonary complication, for, from the man's statement, he had only presented cough and symptoms of lung trouble for a few days prior to admission.

We, therefore, considered this more as a lung case than as a fever case, for the remittent had largely passed away. Now, gentlemen, notwithstanding all the means employed, the lung complication became more marked, dullness became more evident, and extended over the whole of the right lung, the usual impaired resonance of pneumonia. But the point that I wish to impress upon you is this: at no one period in the disease did we obtain a pure, distinct blowing or tubular respiration; it was always a little obscure, with expiration prolonged, and, with increased vocal fremitus; though we regarded the case, on the whole, as one of pneumonic consolidation. The day before his death, which occurred yesterday, he had a great increase in dyspnœa. No murmurs were detected in the heart, but the dyspnœa was due to obstructed circulation.

Here are the specimens. Look at this right lung; it looks like liver, not like lung. It is so red, so firm, so dense, so completely consolidated, that it gives us a marked illustration of true or croupous pneumonia; very different from the pneumonic lung that you saw a few moments ago, which was only a bastard pneumonia. This is the true disease, in which there is a deposition of lymph in the air-cells, solidifying the lung so that it will sink in water. See how large and dense it is, like liver; hence the term "hepatized," often applied to this condition. What do we find in the other lung? There is congestion at the lower part, but this is not the reason I wished to show it to you, but because it is an excellent illustration of emphysema—vesicular emphysema, in which the air-cells are greatly distended by air, especially along the border of the lobe; the lung tissue is spongy. Here we have pneumonia with complete hepatization in one lung, and marked emphysema of both lungs. A combination very likely to prove fatal. The spleen is large; I only mention it in connection with the malarial history. The heart contains clots formed in the left ventricle, as well as on the right side, and there is every reason to believe, from their hardness and fibrinous character, that they are ante-mortem clots, that they had been forming for a day or two, and that they possibly were the cause of the increasing dyspnœa.

Now, why had we not marked signs of pneumonia? Why did we not have ordinary bronchial blowing respiration and well-transmitted râles, from this evident complete consolidation? Why did we rather incline to the diagnosis of pneumonia only; because it fitted into the case better than anything else, because of the dullness, the

râles, the well transmitted voice and increased fremitus? Indeed, the disease acted more like the pneumonia of a continued fever than a true, frank pneumonia?

Gentlemen, the only explanation that we can give here of the absence of the signs of perfect consolidation (tubular breathing) although the lung is completely hepatized, is the co-existence of emphysema. The lung had been in a condition of very great and long-continued distention of the air vesicles; the pneumonia attacked a lung altered by emphysema. There was dullness, but the amount of dullness was not so great during life as you would expect. But the most instructive part is the absence of tubular or bronchial breathing. With this consolidation we ought to have had the most marked tubular respiration, almost metallic in its whiff. How explain its absence, with the marked consolidation which this lung shows? You do not find the almost complete consolidation around the bronchial tubes in this case of emphysema which is necessary to produce bronchial breathing, characteristic of uncomplicated true pneumonia. So that this case of lung inflammation occurring during remittent fever, or chronic malaria, is interesting, from the fact that the physical signs of pneumonic consolidation were modified by the pre-existence of emphysema in both lungs, for the affected lung was undoubtedly in the crippled condition so well marked in this left lung; a complication, moreover, that must always render more grave the prognosis.

Relapse in Typhoid Fever, as Indicated by Transverse Markings on the Nails.

You will remember that early in these cases of typhoid fever I showed you two cases where the relapse was nearly over, and I called your attention to the marking upon the nails, owing to imperfect development during the fever. Patrick J., at that time, was at the height of the relapse, and I brought him before you particularly to illustrate relapse in typhoid fever. I bring him now before you to show you that he exhibits very plainly the characteristic marks upon the nails; in this case a double line is seen. You observe the first white mark from the original attack, and the second is just grown out. You can see by the nails that the man has passed through two fever seizures. So that, in making a report of recovery in this case, we observe, as a matter of interest, that he has a double line running across the nails of his fingers, which is best seen in profile.

Malario-Typhoid Fever, with Relapse Having the Character of True Typhoid—Treatment.

In concluding to-day's clinic, let me bring before you this man, who seems fated to come before you; he is always presenting something new. Cornelius J. is one of the most instructive cases in the ward—a case of malario-typhoid fever, typhoid with a malarial complication, not a typho-malarial fever. This man, who has now been presented twice before you, became much better—in fact, he got pretty well; his spleen went down, his abdominal symptoms disappeared, or nearly so, a little diarrhœa remaining; his temperature fell to the normal, you see, even a little below, to what we call a sub-normal temperature; it was 98°, as is shown by this temperature chart. It remained normal, or a little below, for nearly a week, at the end of this malario-typhoid fever, when suddenly—notice this enormous rise—from 98°, in a day and a half, it reached again 103½°. Since then it has been a fever temperature, with some daily exacerbations and remissions, but not below 100°. Here is the characteristic feature of the temperature in a relapse of typhoid fever: Going up suddenly, after remaining normal for several days, attaining its maximum in less than forty-eight hours. With this reappear the usual symptoms of typhoid: The tongue, which had been cleaning, has become again red and lightly coated, his diarrhœa has come back (he had six stools in twenty-four hours, and within the last twenty-four hours he has had three stools of a loose character, and that although he had been taking remedies to keep the bowels in check). Moreover, what will be most interesting to you, the spots have returned. At the lower part of the chest we have a characteristic rose rash reappearing; they were seen on the second day after the occurrence of the fever. Therefore they constitute an early eruption.

Now, could you have a better illustration of what the symptoms of relapse in typhoid fever are—rapidly returning high temperature, attaining its maximum speedily, eruption shown on the second day, not lingering until the end of the first week, as in the first attack, but coming back quickly, and diarrhœa? But what from? Was there any indiscretion in diet? This I cannot say; I do not know of any change in the diet, but sometimes patients have things smuggled to them by their friends, apples and things of that description; but I do not learn of anything of that kind here. I look upon it as a case of relapse in typhoid fever, from re-absorption from his own intestines of the typhoid fever material.

The treatment shall be mineral acid, moderate doses of quinine, keeping the bowels in check by opium suppositories, if necessary, increasing the stimulant again, with a restricted diet; this shall be the treatment here continued, and it does not differ materially from the treatment of the first attack.

Medical Societies.

IOWA UNION MEDICAL SOCIETY.

The semi-annual meeting of the Iowa Union Medical Society, embracing the counties of Linn, Jones, Cedar, Scott, Benton, Delaware, Marshall, Tama, and Buchanan, with a total membership of seventy-six, met in Cedar Rapids, Iowa, December 14th, 1880, Dr. Geo. P. Carpenter, of Cedar Rapids, in the chair; twenty-nine members present. Drs. J. F. Escher, H. L. Green, S. C. Koontz, S. Cummings, and E. M. Keyes were elected to membership.

Dr. A. Reynolds, Superintendent of the insane asylum at Independence, gave an excellent demonstration of the anatomy of the brain, on a

finely-prepared specimen, showing the location of Ferrier's centres of motion, sensation and special senses. It was listened to with marked interest.

Dr. G. L. Carhart, of Marion—who reported at the last meeting a remarkable case of general anasarca, cured after paracentesis abdominis, by calomel in alterative doses, aided by cream of tartar, sulphate potassa and squills, followed by digitalis and quinine, and who was requested to report the condition of his patient at this meeting—reported that her health remained excellent, and that he considered her cure permanent. This case was remarkable on account of the immense size the woman had attained, measuring four feet, eight inches in circumference over the abdomen, the amount of fluid yielded after tapping, the wound discharging freely for several days, and her final recovery under treatment, after having been given up as incurable by her former attendant.

Credentials were issued to the following members as delegates to the Iowa State Medical Society: Drs. J. C. Batdorf, J. W. Carson, H. L. Green, J. W. Lagrange, I. A. Packard, J. F. Escher, A. B. Reed, and S. Keith.

Dr. L. J. Adair, of Anamosa, read a report of several cases of exophthalmic goitre cured by the internal administration of tr. digitalis and hypodermic injection of ergotin into the thyroid. (p. 89.)

Dr. G. R. Skinner, of Cedar Rapids, reported a case of the same disease, treated on about the same plan, as cured after change of climate and general surroundings. The cause he regarded as of nervous origin in this case, and was maintained by unpleasant surroundings.

Dr. J. W. Firkins, of Fairfax, read a report of a case of puerperal convulsions in a girl 15 years of age. The first convulsion occurred about the second month of gestation, after the patient had taken immense doses of tansy to procure abortion. No convulsions then occurred until labor set in. The case was discussed by several members, the majority of whom inclined to the opinion that the convulsions were hysterical rather than puerperal eclampsia.

Dr. E. Burd, of Lisbon, read a report of a case of puerperal convulsions in a multipara, following delivery of twins. The patient had for years been affected with kidney disease, and at the time of her confinement was in a condition of general œdema. After recovering from the convulsions the disease of her kidneys ceased, and her health is now better than it has been for years, except that her memory is poor.

Dr. A. Jasper Jones, of Blairstown, read an essay on the therapeutics of chloral hydrate.

Dr. E. H. Hazen, of Davenport, read an interesting paper on traumatic cataract, giving illustrated cases, and urging the importance of the early use of atropia in all cases of injury to the lens.

Dr. J. Doron, of Mt. Vernon, made some remarks on the present State Board of Health law, criticising some of its provisions rather severely. Considerable warm discussion followed.

Dr. Doron offered the following resolution, which was lost:—

Resolved, That the matter of physicians' fees for attendance on pauper patients be referred to the township Trustees, by the consent of the Board of Supervisors.

Dr. J. W. Lagrange proposed the following, which was carried:—

Resolved, That a committee of three be appointed by this Society to confer with the Board of Supervisors of Linn County, to adjust the matter in regard to pauper practice.

Chair appointed Drs. G. L. Carhart, J. S. Love, and J. W. Lagrange.

Dr. J. C. Batdorf, of Mechanicsville, read an essay on the hypodermic treatment of hemorrhoids, with cases. The formula which the doctor uses is:—

R.	Carbolic acid crystals,	ʒ ij
	Pure olive oil,	gtt. xxv.

Dissolve the acid by heat, and add the oil.

He treats but one pile tumor at one sitting. He reports more than fifty cases treated, all of which were cured, and no bad results followed.

Hypodermic Treatment of Hemorrhoids with Carbolic Acid.

A little more than three years ago I began the treatment of pile tumors with carbolic acid, by hypodermic injection. I was induced to resort to this method of treatment by reason of the fact that all other systems of treatment of this very prevalent and painful affection were objectionable, in consequence of the danger attending them, or their inefficiency in effecting a radical cure.

It is true that well-written articles have appeared from time to time in the medical journals, inveighing against this method of treatment, as fraught with dangers equal to those attending the ligature and knife. Two or three deaths were reported, supposed to have been caused by embolism, while a large per cent. of the cases treated had painful abscesses form in the anal region. Certainly these were formidable objections and must be overcome, or this method of treatment abandoned. How was this to be accomplished? When a pile tumor is injected with carbolic acid, the primary effect is the coagulation of its fluid contents. If a weak or highly diluted preparation of acid is used, coagulation takes place slowly and imperfectly, and it is possible that a small coagula may find its way into the circulation and give rise to embolism. It is more than probable that the formation of abscesses is attributable to the same cause, viz: imperfect coagulation and the absorption of acid. If rapid and perfect coagulation can be secured, embolism is a physical impossibility. Believing this theory to be sound, I have conducted my practice accordingly; and of more than fifty cases treated, all are cured, and no untoward symptoms presented themselves, except in two cases, where I was compelled to use a ten per cent. aqueous solution of carbolic acid—not being able to procure the crystal—in which small superficial abscesses formed in the anal region.

* * * * * * * *

It is important to inject the tumor near its centre, in order to avoid perforating the coats of the bowel, which might be attended with serious results. * * * * * * *

The secondary effect of injecting the acid is ulceration and sloughing of the pile tumor.

The formula which I am in the habit of using is as follows:—

℞. Carbolic acid cryst., ʒ ij
Pure olive oil, gtt. xxv.
Dissolve the acid by heat, and add the oil.

Should the acid crystallize on cooling, I do not increase the per cent. of olive oil, but I re-dissolve before using. I sometimes employ a saturated solution of acid, adding five drops olive oil to the ounce of acid. So far as I am able to determine, both formulæ are equally efficacious. The object in view for adding olive oil is to render the action of the acid more mild, which I believe it accomplishes without interfering with its powers of rapid coagulation. The number of drops to be injected into each tumor will vary from eight to fifteen, owing to the size of the tumor.

In order to limit the constitutional disturbance and suffering of the patient to the lowest possible degree, it is advisable to treat only one tumor at a sitting. It is rarely necessary to inject the same tumor a second time. Where but one tumor exists the patient is usually cured in thirty days, having required but a single treatment.

There sometimes remains a hypertrophied condition of the mucous membrane of the bowel after the tumor is removed, giving the patient no little annoyance by its protruding at time of defecation, leading him to suppose there is another tumor, or that the first one is not cured. This condition will pass away spontaneously after a few weeks, or it may be hastened by the application of carbolic acid and glycerine, in equal parts, applied by means of lint or carded cotton, with dressing forceps.

During the entire treatment the bowels must be kept in a soluble condition with castor oil or other laxative, the parts kept clean by the use of soap and soft water, and undue irritation or inflammatory action held in check by the application of ground linseed or elm poultice.

Dr. G. E. Crawford, of Waubeek, read a report of a case of trephining the mastoid in suppurative inflammation of the middle ear. The case was one of four months' standing, in which the ordinary treatment had been persistently tried without any improvement. The discharge from the ear was profuse and the pain most excruciating, requiring enormous doses of morphia hypodermically to modify it. Perforating the mastoid process resulted in immediate and very marked relief of all the symptoms. Patient improved rapidly for several days, when, during the doctor's absence, the tent came out and the wound was allowed to close. Pain and swelling returned, which was relieved immediately on re-opening the wound. Patient made a rapid and perfect recovery, with only partial loss of hearing.

Dr. Hazen remarked that the scalpel answered a good purpose in opening the mastoid cells, being always careful to cut upward, and thus avoiding the danger of injury to the vessels of the neck, should the knife slip.

Dr. G. P. Carpenter, of Cedar Rapids, read a report of a case of ulceration of the stomach.

On motion the Secretary was directed to furnish a copy of the minutes to the Medical and Surgical Reporter, for publication.

Treasurer's report was read, showing a balance of over fifty dollars in the treasury.

Edwin Burd, m.d., *Secretary.*

Editorial Department.

Periscope.

The Origin of So-called Filth Diseases.

Dr. H. N. Burr, of Walworth, N. Y., now of Rutherford, N. J., writes to the Boston *Journal of Chemistry*:—

Dr. W. H. Corfield, as quoted in the *Journal*, of February, 1880, in an article on "Sanitary Fallacies," says that among these fallacies "is the notion that the poisons of cholera and enteric fever and diphtheria may originate anywhere, at any time, under suitable conditions." It has been well established, in his opinion, that these diseases cannot originate *de novo*, however filthy the surroundings may be, but arise, in all cases, from "the virus-laden discharge of the intestinal canal" of the persons who already have the disease. This seems extravagant language and a hasty conclusion, to me, who for a number of years have been engaged in practicing medicine in the country. I meet with single instances of enteric fever and diphtheria where I am unable to trace out any cause except the unhealthy surroundings.

These repeated instances, in the face of such instruction from teachers of sanitary science, put us to thinking and searching for the hidden source of the disease, and our efforts are fruitless so far as confirming the propositions laid down by our teachers. I will give two or three instances of cases where the evidence has been in favor of the spontaneous origin of these diseases when surroundings are favorable.

A few years since I attended a family of Hollanders, consisting of a man and wife and several children. I found them with diphtheria of a most malignant type. One child died soon after I saw it, and others were ill with it. The room was full of a terrible odor from the fauces. Two of the children died; the others recovered; some of them were paralyzed, and one little girl was blind for several weeks. Investigation revealed no knowledge of the disease having been there previously. It was in mid-

winter, and the weather had been, and was at this time, very cold, although there had been times of moderate weather and thawing. The family lived at the foot of a hill, and used water from a ditch that ran by the house. When we examined the cellar we found that a large quantity of potatoes had been stored there, to keep for the spring market. The cellar had not been made secure against cold, and a large part of the potatoes had been frozen. The warm weather had extracted the frost, and they had for some time been a rotten mass. I could come to no other conclusion than that they must have been the original source of the poison. It may be said, on the other hand, that in our investigation we had not gone back far enough, or that our informants had forgotten some of the facts in the case. In what followed we may find arguments in favor of the other theory, or that of Dr. Corfield. In the spring this family removed from this house, which was thoroughly cleansed and rented to another tenant. This man had several children, who, in a few weeks, were attacked with the diphtheria, and three of them died. The rotten vegetables had been cleared from the cellar, and yet the germs must have remained in the house, waiting for a convenient soil in which to propagate. The disease in the first family we cannot account for, but we can for that in the second family. The first may have originated from the unhealthy surroundings, while the second must have sprung from germs which remained in the house.

In another instance enteric fever occurred in a family near town. The mother and little girl were taken with this fever, the child being first taken; the father did not have it. I was called to attend the child, and she passed through four weeks of the fever before convalescence was established. The mother was taken two weeks after the child, and likewise passed through four weeks before convalescence. The surroundings were healthy, to all appearances, and the house was well drained; but on visiting it one evening, just after nightfall, I was surprised to find the air filled with a foul odor, which I at once recognized as coming from a privy. Inquiry revealed the fact that the vault had not been emptied for a year or more. It was but a few rods from the back door and from the living room, and the yard was used as a playground by the children. I examined the privy and found its contents near the top of the ground, and running out underneath the building. The little girl had used this place to play in, and the mother informed me that she spent a good part of the time there, with her playthings, during the summer. The sickness was in the latter part of summer. These were the only cases in the neighborhood that year, and there had been none for four years before. The father was a teamster, and away from home most of the day, and therefore less under the influence of this poison. In this case the fever must have been generated at home.

Some cases can unquestionably be traced to morbid discharges from enteric patients, but in the country and in villages we often meet with cases like the above, and then what conclusion must we come to?

Treatment of Acne Vulgaris

The *Practitioner* gives Dr. Sesemann's treatment of this disease. It occurs most frequently between the ages of sixteen and forty. The disfigurement which it produces is such as to amount to deformity, and this in girls. Hebra believes that it is a more obstinate affection than even eczema. For several years Sesemann has employed a plan of treatment which has yielded excellent results, and which is a combination of the various methods used by Hebra, Auspitz and Ellinger. In mild cases, where the eruption is limited, lotions with sulphurous or mercurial washes (Kumrenfeld's wash, or Gowland's liquor) are sufficient. When the inflammation has passed from the sebaceous follicles, however, to the surrounding cellular tissue, tumors of the size of a hazelnut, or it may be, of a chestnut, are found, from which sebaceous material is exuded for a long period, and which leave, on healing, cicatrices and frequently pigmented indurations, which are very difficult to get rid of; under these circumstances the excretory duct of the gland which is blocked by the excessive secretion acts as a foreign body to the surrounding parts. It is, therefore, absolutely necessary to render it permeable, or to cause a return of the secretion if it has been arrested. With this end in view, the author removes, as far as possible, all sebaceous and epidermic detritus, by means of an ivory or mother-of-pearl instrument, which resembles a "folder," with delicate rounded edges. By pressing upon the two sides of the duct with this instrument, the sebaceous material is made to escape, and the affected part is then scraped lightly with a sharp spoon. When the inflammation is deep seated, an incision is to be made with a bistoury, and the pus evacuated by pressure, since if this precaution be neglected the eruption quickly reappears. Any small hemorrhages which may occur are readily controlled by the use of salicylated wadding. Some patients, especially women, object to this method of puncture, but the operation causes so little pain that when it has once been performed the subsequent pricks are borne without fear. After the puncture and the scratching have been finished, the face is carefully explored with the bulb of the index finger, to discover, if possible, any suppurating points which may have escaped notice. The acne spots are distinguished by the fact that they are not soft, and that they do not fluctuate, as well as by their brownish-red color, which appears to invade the surrounding skin. After the surgical treatment is complete, poultices and lotions should be applied. The surface should be first thoroughly cleansed with soap, after which an ointment, composed of one part of spermaceti mixed with three parts of fat, should be applied. In the evening, after the reaction of the skin has disappeared, the acne spots are to be covered with a paste of sulphur, glycerine and potassium carbonate, which is left on all night, and should be removed from the larger points as soon as any symptoms of ulceration or inflammation show themselves. As soon as the face has become smooth again, brisk friction is to be made, at first with soap alone, but afterward with soap and sand; it is best to rub the face with black soap

dissolved in water and mixed with fine white sand. The treatment appears cruel, but it is generally well borne, and affords great relief to the patient. The redness of the face rapidly disappears, especially if the liniment mentioned be employed, but it is well to apply diachylon from time to time, and to leave it on all night. After the treatment is finished, the patient should for a long time continue to use the lotions and apply the liniment. Dr. Sesemann frequently mixes chrysophanic acid with his paste, since he prefers it to sulphur, as being less irritating to the skin, and because it does not leave behind it brownish marks.

Treatment of Cerebral Rheumatism by Cold Baths.

M. Woillez has read a memoir on this subject, before the Academy of Medicine at Paris. It was Bourdon who first called attention, in 1823, to an affection of the brain occurring in rheumatism, which rapidly proved fatal in all cases.

During the course of an acute rheumatismal attack there supervened a state of cerebral excitation, coinciding with a diminution of the pain etc., in the articulations, and followed by delirium and coma; the termination proving constantly fatal. What might be the nature of the malady; the symptoms did not follow the course observed in meningitis; and again post-mortem examination gave very incomplete results, for no constant lesion was found; in some cases there existed anæmia, in others hyperæmia of the meningeal membranes, with or without serous effusion. Very often microscopical lesions alone were found; so that it came to be regarded as an independent brain affection, or as a nervous alcoholic or febrile delirium; it was Bricheteau who first considered it as a metastasis.

As regards the treatment of the affection, two periods may be distinguished: 1st. That extending from 1859, date of the classification of the malady, up to 1870, when the thermometer threw new light on the question; and 2d, from 1870 to our own times. During the first period, cerebral rheumatism had always a fatal issue, the physician who made the diagnosis observed the approach of the fatal termination without being able to intervene efficaciously.

This complication is not absolutely rare. M. Vigla remarked that out of sixty-five cases of rheumatism five terminated in these cerebral complications. M. Woillez himself observed several cases supervene in patients he had considered in convalescence on account of the disappearance of the articular troubles; there was slight delirium, and death always ensued. In seven cases only recovery took place, and the diagnosis was not perfectly certain in some of these; in others, endocarditis was present; and finally, in two cases baths had been employed. Afterwards, in 1870, when it was observed that a considerable rise in temperature (to 104° and even to 106°), coincided with the development of the cerebral symptoms, cold baths were thought of, first in England, later in France. In 1874, M. Maurice Reynaud had a first success; then equally favorable results were obtained by MM. Blanchet, Ferréol, Vallin, and Woillez. In the thesis of M. Du Castel, thirty three observations are cited; in nineteen cases where no treatment was instituted, all proved fatal: while out of fourteen cases where cold baths were used, ten recovered. M. Woillez, has had favorable results in five cases from this treatment.

Sodium Phosphate in Habitual Colic.

This remedy is recommended by Dr. R. N. Taylor, in the *Medical Herald*, December, 1880. He writes:—

It has fallen to my lot to have been beset with a number of patients who would persist in having colic at the most inopportune moments imaginable; first one, and then the other, then still another one, these colicky friends of mine were constantly interfering with my professional engagements, and, what was more important still, with my hours of rest. Without entering into a discussion of the pathology of these cases, I beg leave to present, in brief, the history of one of the worst I have ever seen, together with the treatment, which resulted in completely warding off the attacks in this case, as in all others in which it has been carried out:—

Mrs. H., aged seventy-two years, for fifteen years has been the subject of attacks of cramp colic, recurring at first every two or three months, but for six years past coming on every two weeks, sometimes every week; has taken nearly everything in the materia medica, both at the hands of regulars and quacks, without any benefit, the attacks continually recurring, and that without any regard to errors of diet, coming on at nearly regular intervals, no matter how careful or how particular she might be in regard to her diet.

During the paroxysms of colic the pain is most atrocious, accompanied by cramping pain in the extremities, nausea, vomiting, etc., to such an extent as to demand my immediate presence, armed with the hypodermic syringe.

This patient was put upon the use of phosphate of soda, grs. xxx, ter in die, before meals and—the fees stopped! She had no more attacks of colic. If she omits the use of soda for a length of time, say six or eight weeks, she will have a few premonitory twinges, the precursors of a more severe attack; but immediately obtaining a supply of the drug, she is safe so long as she continues to use it, and for some time afterward.

This is not an isolated case, but one of several that could be adduced in favor of the use of phosphate of soda in the colic habit; but it is deemed useless to multiply instances upon so trivial a matter. Suffice it to say, that I have never failed to see the administration of phosphate of soda followed by a complete cessation of the attacks of colic, and my experience in the use of this drug has now become quite extensive.

By the city practitioner, who can readily obtain the Vichy and other fashionable alkaline waters, and who moreover is supposed to keep himself abreast with the progress of the times, this will not be received as valuable information. But it is furnished for the benefit of the country doctor, who will find in the phosphate of soda a cheap and valuable substitute for the medicinal waters, such as the Vichy, etc., and one that will not disappoint him.

In these cases I generally begin with grs. xxx

three times a day, and if that amount produces much irritation of the bowels, indicated by frequent small discharges, attended perhaps by some tenesmus, I diminish the dose to xx or xv grains. It is to be administered before meals, from a half to one hour, in a glass of water, and when thus dissolved it is not at all unpleasant to the taste.

Practical Methods of Antiseptic Treatment.

M. Lucas Championnière, perhaps one of the most able defenders, in France, of Lister's ideas, gives the following excellent counsel to the busy practitioner, unable to follow strictly the rather complicated methods of the great English surgeon. The practitioner must first banish from his practice substances already in a state of putrefaction—cataplasms, rancid oils, etc.

The most convenient substance for general antiseptic use is certainly carbolic acid. But carbolic acid requires a small quantity of alcohol, or better, of glycerine, to aid in dissolving it, when added to large proportions of water. The two following solutions are found most convenient in practice:—

I. STRONG SOLUTION.

℞. Ac. carb. (crystals), 50 grams
Glycerinæ, 50 or 75 grams
Aquæ, 1000 grams. M.

II. WEAK SOLUTION.

℞. Ac. carb., 25 grams
Glycerinæ, 25 grams
Aquæ, 1 litre. M.

Or a vial containing a solution of fifty grams of carbolic acid in fifty grams of glycerine may be used, the strong solution being obtained by adding the contents of the vial to one quart of water, the weaker by using two quarts of ordinary water.

These two solutions suffice for the antiseptic surgery in ordinary practice; the feeble solution serving to sponge out the wound, and particularly for saturating the ordinary dressings; the strong solution is used for cleansing the instruments, and for sponging the wound just after the operation is finished. In treating a simple incised wound, it should first be sponged with the strong solution, sutures passed, and one or two small pieces of rubber tubing placed upright in the wound; then a small strip of oiled silk should be placed over the line of reunion, then a thick dressing of charpie or lint, saturated with the feeble solution, and over all a strip of oiled silk.

For ten years M. Championnière has treated abscess—even perinephretic and mammary abscess—without having recourse to poultices After the abscess is opened he injects the cavity with the strong solution; he then places a short tube of caoutchouc upright in the cavity and directly over the incision, he applies a dressing of charpie or lint saturated with the weak solution, then a covering of oiled silk.

MM. Trelat and Rochard extolled this method of treatment without cataplasm at the recent Medical Congress of Rheims. It is astonishing to observe how small a quantity of pus is formed; and even the pain of the phlegmon is beneficially modified almost as much as by a cataplasm. Mammary abscess thus opened and treated rarely becomes multiple.

It will be seen that the principal indications for antiseptic treatment may be fulfilled without difficulty, and that we may thus guard against the complications ordinarily met with in surgical practice.

Topical Uses of Iodoform.

In a scientific conference, at the Louvain Hospital (*Arch. Med. Belges*), M. Bourdeaux, army surgeon, spoke favorably of the topical application of iodoform. He cited a case of phagedenic chancre which had been treated, ineffectually, with different preparations. He did not wish to cauterize, fearing to induce inflammation of the lymphatic glands and bubo; he, therefore, applied iodoform, in very fine powder, to the chancre.

By using a solution in ether the iodoform is deposited, in the state of impalpable powder, on the surface of the sore, after the evaporation of the ether. The local action of iodoform is not as an irritant; it is probable that the medicament acts by absorption; however that may be, after two days the chancre was beneficially modified, and after eight days completely cicatrized.

M. Bourdeaux also employed iodoform as an antiphlogistic and resolutive, in blenorrhagic orchitis. In one case of chronic orchitis, with little pain, he employed an ointment containing four grams of iodoform in thirty of lard, with the effect of banishing the pain, although the swelling persisted. In another case of acute orchitis, with considerable swelling, and so much pain that the patient was unable to walk, he first used mercurial inunctions, followed by cataplasms, and the next day, as there was no amelioration, he applied six leeches over the spermatic cord. As there was no modification for the better, he ordered the iodoform ointment to be applied, and the scrotum to be elevated by a suspensory bandage. After the first application, the pain disappeared, and the patient was enabled to go about his daily occupations, which obliged him to remain standing almost all day. The testicle remained engorged but the acute pain was no longer felt.

In a case of neuralgic pains in the testicle, supervening after a blow, iodoform in ointment has had a marked sedative effect.

In commenting on these observations, M. Gosse cited a case of orchitis where an ointment containing iodide of potassium was applied to the surface, previously treated with mercurial inunctions. Gangrenous inflammation ensued, affecting the entire surface to which the applications had been made M. Gosse attributed this result to the formation and caustic action of iodide of mercury.

Successful Case of Cæsarean Operation.

M. Caternault, of Longué (*Le Concours Med.*, Dec. 4th), reports in his practice a case of hysterotomy terminating successfully for mother and child. It was in a scrofulous young woman, of twenty eight years of age, lame from hip disease, presenting very narrow transverse diameters of

the pelvis. Her first child was extracted at term, with the forceps, and with such difficulty that the child succumbed. She was again at full term, and it was found impossible to introduce the forceps. Hysterotomy was determined on and performed without chloroform, on account of her exhausted condition. An incision about ten inches in length was made in the abdominal walls, commencing just below the umbilicus; little blood escaped, and an incision of almost equal length was made on the anterior walls of the uterus. The infant was found in the first position, and was extracted, with some difficulty, through the contracted walls of the uterus, it being found necessary to prolong the incision upward around the umbilicus. A dose (two grams of ergot was given, and in a few minutes the placenta was delivered through the uterine incision. The abdominal cavity was then washed out, one suture passed at the middle of the uterine wound, and four profound and five superficial sutures passed in the abdominal parietes, a space of three inches being left at the lower part for the passage of a tube of caoutchouc. The operation was performed with all the antiseptic precautions, and all went well until the sixth day, when a purulent liquid escaped from the vagina; there was some delirium and general malaise, but in a few days her condition improved, and gradually her health was completely reëstablished. The child, also, is living and in excellent health.

Hysteria as it Affects the Muscles.

Some observations on this are made by Dr. W. T. Sparkes, in the Chicago *Medical Journal and Examiner*, from which we extract as follows:—

Spasmodic stricture of the urethra, caused by intense emotional excitement and accompanied by various hysterical phenomena, is so commonly met with in ordinary practice that it scarcely escapes the attention of the physician or surgeon. The diagnosis of these cases is not very difficult to obtain, if close attention is paid to the clinical history of the patient. It will generally be found that there have been other indications of the hysterical conditions present; that these contractions have made their appearance at other times, and, like "phantom tumors," have duly disappeared. One case which I have had under my care the last year, is that of a woman, thirty five years old, married, with two children. This lady has frequently called my attention to a tumor situated in the posterior part of the latissimus dorsi muscle. Several times I have noticed an intense contraction of the muscle, at other times none whatever. These contractions seem to be produced by a power of the will or from a diseased functional disorder of the brain. Another case is that of a girl thirteen years of age. When first called to see her, my observation was that it was a case of wry neck, but upon a close diagnosis I discovered an intense contraction of the right sterno-cleido mastoid muscle, and the head was drawn violently in the direction opposite to that which had formerly existed. The affection had developed suddenly, so far as she knew, without obvious cause, and was unaccompanied with pain. Her general health up to this time had been good. The treatment consisted of plenty of fresh air, occasional drives, and cold baths. Medically the bromide of zinc proved efficient in relaxing the tension of the muscle. The formula was as follows:—

℞. Zinci bromid., ℥ ij.
Aquæ dest., ℥ ij. M.

Sig.—Ten drops three times a day, increasing a drop at a dose for each day.

I increased the dose until she was taking about forty drops three times a day.

Another case was that of a young married woman. I was called in early one morning, and found her laboring with what she presumed to be a miscarriage. The symptoms, on entering the room, led me to think she was in the third stage of labor, with the pains coming on from five to ten minutes. Upon examination I did not observe any dilatation of the os uteri, nor the least contraction of the uterus, but severe contractions of the abdominal muscles. I watched the case closely for nearly an hour, and left, fully convinced that it was purely hysterical. I gave full doses of bromide of potassium, and in less than twenty-four hours all symptoms had subsided, and there was no further trouble until confinement.

Cutaneous Eruption from Quinine and Cinchona.

Dr. Van Harlingen describes these in the *Archives of Dermatology*:—

Although quinine and the preparations of bark have been in constant and extensive use for the past sixty years, yet comparatively few cases of eruption due to the use of this drug have been reported until within the last few years. As if to make up for lost time, however, a very large number of observations have been published of late, most, if not all, of which are quite authentic, and which place quinine among the drugs which are liable to cause eruptions in certain individuals.

The prevailing type of quinine eruption is erythematous, closely resembling the rash of scarlatina or of measles. It first shows itself over the face and neck, but soon becomes diffused over the whole surface of the body. In exceptional cases it may not become generalized; sometimes on desquamation the epidermis of the hands and feet is shed as a whole. Occasionally the quinine eruption may be papular in form, sometimes resembling erythema multiforme papulatum, or more frequently urticarious. In this class of cases, according to Morrow, there is more or less œdema, with distressing burning, tingling, and itching. Occasionally vesicular eruptions have been reported as resulting from the ingestion of quinine, although such eruptions are usually caused by the external irritative effects of the drug, as in many of the cases cited by Bergeron and Proust. Dr. F. N. Otis related, at one of the meetings of the New York Dermatological Society, in 1877, a case where two or three grains of quinine provoked an eruption resembling that from poison ivy. Panas, quoted by Bergeron and Proust (*loc. cit.*), affirms that the administration of large doses (two to three grams) of quinine has provoked an eruption

presenting the characters of the bullæ of pemphigus.

Morrow has also collected five cases where hemorrhagic eruptions were produced by quinine. In one of these, that reported by Gauchet, so small a dose as ten centigrams continued four days, produced purpura with buccal hemorrhage, principally from the gums. The patient in this case said she had taken the medicine before, and that it had always caused her to spit blood. Briquet gives the case of a patient who, after taking three grams of quinine daily for some little time, showed large ecchymoses on the buttocks and thighs, with a generalized but not abundant petechial eruption over the surface of the body.

In a case reported by Schuppert, six-grain doses produced an intense localized dermatitis, with commencing gangrene of the scrotum. In one of Köbner's cases, quinine always produced an erysipelatous eruption of the scrotum. In several other cases this special tendency to irritation of the skin of the genitalia is noted.

Iodide of Potassium in Typhoid Fever.

Writing in the Pacific *Medical and Surgical Journal*, for November, 1880, Dr. Oatman announces that iodide of potassium is "as much a specific in typhoid as quinine in intermittent fever." His exact plan is this:—

An adult with uncomplicated typhoid fever may take five grains of iodide of potassium every three hours, in a little sweetened water. Also every three hours one dessertspoonful of the following recipe, viz:—

℞. Ol. terebinth.,			
Tinct. anisi,	āā	f. ʒj	
Vitel. ovi,		No. ij	
Sacchari,		ʒij	
Aquæ puræ,	ad	℥ ij.	M.

Ft. emulsio.

Sig.—This emulsion may be taken between the doses of the iodide.

If the skin is quite dry, with very frequent, tense pulse, with restlessness, I usually give, not veratria, for that article seems to have no curative effect on any fever, but the ol. chenopodii. The anthelmintic property of this article I think by no means its most valuable quality. Indeed, it is about the only article I have ever found that will relieve the conditions last stated readily. I have long considered the ol. chenopodii as a pure sedative, diaphoretic and soporific, without any narcotic effect. The medicine may be incorporated with the emulsion in equal quantities with the ol. terebinth, which will cover the disagreeable taste. Or it may be given mixed with syrup and tinct. anisi and given with the iodide in doses of five drops. Also I give sub. mur. hydrargyri, grs. vj, made into four powders, one to be given with every alternate dose of the emulsion and only every second or third day, as indicated. The above remedies I commence simultaneously and continue the same till convalescence ensues, when I gradually diminish the doses and give them at longer intervals. If there is costiveness I incorporate a little castor oil with the emulsion; if diarrhœa, which is very rare, give syrup rhubarb and prepared chalk, but do not discontinue the other medicines. Delirium and subsultus rarely occur; the chenopodium seems to prevent those conditions. The resort to a generous diet may be sooner than under the old treatment, as the chylopoietic system is more improved and better able to perform its functions.

Reviews and Book Notices

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. E. T. Gaillard has recommenced the publication of the *American Medical Biweekly*, which formerly appeared in Louisville. It is now issued in New York city, where the editor resides. It was always well filled with readable matter, and no doubt will continue so to be. Its address is Box 1124, New York city.

——Judge Tourgee, in a popular book called "A Fool's Errand," gave one aspect of life in the South; the other side of the picture is forcibly presented by Wm. L. Royall, Esq., in a pamphlet entitled "A Reply to 'a Fool's Errand.'" It is published by E. J. Hale & Son, New York city.

——"Where to Go in Florida" is the title of an appropriate little book, pleasantly written and prettily illustrated, by Daniel E. Tyler (Hopcraft & Co., 121 South Fifth avenue, New York, pp. 42, price 25 cts.). It contains a great deal of information, and though presenting only roseate hues from the Land of Flowers, and omitting the many disagreeables quite as common as the flowers, yet it can be recommended as a neat and graceful handbook to those who wish to visit the peninsula.

——In a reprint of his article on the Surgical Treatment of Intestinal Obstruction by means of the Operations of Laparotomy and Colotomy, Dr. W. T. Briggs, of Nashville, vindicates the comparative ease and safety of these proceedings. He gives minute directions for their performance, and reports several successful cases.

——The report of the Philadelphia Dispensary for 1879, recently issued, gives the total number of cases treated at the Dispensary and at their own homes, including teeth extracted, at 21,343; prescriptions compounded, 38,008.

The District Physicians report 1528 cases. The number of house patients was 10,844.

This Charity is one of the oldest in Philadelphia, and covers most of the city in its operations.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE PROGRESS OF CREMATION.

It is gratifying to notice the steady although slow progress which the advocates of cremation are making in Europe. The public are beginning to see that it is an extremely rational method of disposing of corpses. The objections to it on the score that it might conceal the traces of poisoning, have been met by the proof that this would, under any circumstances, be most rare, and could be wholly prevented by the adoption of more stringent rules respecting death certificates.

The objections on the score of sentiment are really those which stand in the way of its adoption, yet it requires but few arguments to show how unfounded are these. Certainly the purification of the remains by the cleanly flames is far more agreeable to contemplate than the processes of putrefaction and decay in the ground. The one presents us in a few hours with the mortal remains of our friends in the shape of "scentless and delicate dust;" in the other, if we think of them at all, it is under repulsive and nauseous forms, which we only tolerate through custom. The poetry which surrounds the "ashes" of the departed stands in contrast with the meditations of Hamlet over the body of Yorick:—

"How abhorred in my imagination it is! My gorge rises at it."

"Dost thou think that Alexander looked so i' the earth?

Hor.—E'en so, my lord.

Ham.—And smelt so? Pah!"

The least reflection will convince the thoughtful that those proper sentiments of affection which prompt us to care for the mortal remains of our departed friends are best consulted by reducing the corpse to ashes by incineration.

It is well known, also, that there are many sound sanitary and economical reasons why cremation is preferable to any other plan of disposing of the dead. These were briefly put in an address by the eminent surgeon, Mr. T. Spencer Wells, of London, as follows:—

"Decomposing human remains so pollute earth, air, and water, as to diminish the general health and average duration of the life of our people.

"Existing churchyards and cemeteries are not well fitted as safe, secure, permanent, innocuous places of repose for the remains of our dead.

"The expense of funerals and interment in graves presses unduly upon the means of the middle and laboring classes.

"The present system of registration of death is so imperfect that common causes of preventable disease are not detected; and life is also rendered insecure by the omission of efficient arrangement for the due verification of the fact and causes of death.

"These evils might be mitigated or prevented—(1) if national cemeteries were provided and maintained, under the direction of duly qualified officers of public health, and not left, as now, to be sources of private gain to commercial companies; (2) if no interment were allowed without a certificate of the fact and the cause of death by an officer of public health."

These observations apply as well to the more thickly settled portions of the United States as to England. A complete remedy for all would be cremation, conducted by government or municipal authorities.

As illustrations of the growing acceptance of this method, we may mention that the British Medical Association has presented an address, numerously signed, to the Home Secretary, reading as follows:—

"We, the undersigned members of the British Medical Association, assembled at Cambridge, disapprove of the present custom of burying the dead; and desire to substitute some mode which

shall rapidly resolve the body into its component elements by a process which cannot offend the living, and may render the remains absolutely innocuous. Until some better mode is devised, we desire to promote that usually known as cremation. As this process can now be carried out without anything approaching to nuisance, and as it is not illegal, we trust the government will not oppose the practice when convinced that proper regulations are observed, and that ampler guarantees of death having occurred from natural causes are obtained than are now required for burial."

When will the American Medical Association throw the weight of its official influence in favor of the introduction of crematories into this country, in our great cities?

We have previously mentioned in the REPORTER, that cremation is already legalized in parts of Germany and in Italy; that crematoria have been erected and used in Gotha and in Milan and Lodi, and a society established in Rome. A phrase in the sanitary laws of Switzerland which forbade cremation has been removed, and a piece of ground in the new cemetery at Zürich has been set apart for the erection of a crematorium.

On June 16th last, Professor Polli (whose researches on the antiseptic action of the sulphites and hyposulphites are well known to all physicians), who, in late years, had been one of the most ardent supporters of cremation, who had himself proposed a method, which was the first tried in Italy, had his body, by his own express desire, cremated, and his ashes were consigned to their resting-place with all due solemnity, in the presence of mourning relatives. This cremation was the sixty-eighth which has taken place in Milan, since January, 1876.

Several large cremation societies have been formed in Switzerland. One large society in Holland has several branches. In France, the Paris Municipality has called for designs for the best form of furnace. In Belgium, one society in Brussels has more than four hundred members, and M. Creteur has been thanked by the Government for the successful cremation of the bodies of soldiers killed near Sedan.

So far, in this country, the only incinerations practiced have been those at Washington, Pennsylvania. The method has, however, a brave advocate in the eminent Professor Gross, of Philadelphia, who has written: "There is something eminently repulsive to me about the idea of lying a few feet under ground, for a century, or perhaps, two centuries, going through the process of decomposition. When I die, I want my body to be burned. There is nothing repulsive in the idea of cremation. People's prejudice is the only opponent it has had. If they could be awakened to a sense of the horror of crowding thousands of bodies under ground, to pollute, in many instances, the air we breathe and the water we drink, their prejudices would be overcome, cremation would be taken for what it truly is, a beautiful method of disposing of the body."

Late advices inform us that a society has recently been founded in Paris for the propagation of cremation, which is at present illegal in France, and the names of a number of medical authorities and municipal councillors figure among the general committee. The object of the society is twofold. First, to agitate for legislative measures in favor of cremation; secondly, to encourage scientific research as to the best means of putting it into practice. All those who are in favor of cremation, and who will engage to exert themselves actively in the furtherance of the cause, are invited to join, the number of members being unlimited, and as the annual subscription is small a great many adhesions may be expected. When the first object is attained, and cremation has become legal, the society will change its name to that of Société Française de Crémation, and will devote itself peaceably to the construction of *crematoria* and *cineraria*, and to the gratuitous incineration of defunct members.

NOTES AND COMMENTS.

Accidents after Ovariotomy.

M. Leon Labbé, in a recent séance of the Academie de Médecine, of Paris, concludes, from observing several unfortunate cases, that failure in ovariotomy is due to septicæmia, brought on by stagnation of pus, particularly where adhesions were present, but often when there was none. He advises drainage of the peritoneal cavity in all cases, by means of rubber tubing of

large calibre, the piece introduced being each day shortened.

Several tubes, even, may be introduced, at various depths, according to the situation of the adhesions found during the operation.

This precaution of drainage is indispensable, even when antiseptic treatment has been fully carried out, and particularly when concurrently with the ovarian cyst there exists ascites or multiplied adhesions, which give rise to a consecutive sero-sanguinolent effusion. M. Labbé considers that the respiratory movements tend to force out the accumulated pus through the tubes.

It would seem at first view impossible that the pus can thus ascend to pass out by the tubes, but it will be found that drainage is always preferable to opening the vaginal cul-de-sac, to allow the escape of pus.

Apparent Insusceptibility to the Influence of Nitrous Oxide.

Mr. George Lyddon read a communication, lately, before the Odontological Society of Great Britain, on "The Behavior of Patients during the Administration of Nitrous Oxide Gas." Of the half-dozen cases related, the following were the most remarkable: A clergyman, apparently healthy, though he said he suffered severely from dyspepsia, and actively engaged in the duties of his profession, took the gas; he exhibited no signs of nervousness, but inhaled it freely and well. After taking a considerable quantity he declared it was having no effect upon him, and as this was evidently the case, the attempt was abandoned, and the teeth were extracted without the aid of any anæsthetic. Mr. Lyddon estimated that the patient had inhaled about twenty gallons of the gas, but it had no more effect upon him than if it had been common air. The apparatus appeared to be in perfect order; it acted quite satisfactorily with the next patient operated on, and Mr. Lyddon could not give any explanation of the failure. The same thing happened on another occasion, the patient being a lady; in this case, also, anæsthesia could not be induced by nitrous oxide, so chloroform was substituted, with complete success.

Carica Papaya.

Under this name, says the *Chemist and Druggist*, there has lately been an active inquiry for the milky juice of a Brazilian plant which has been reported on by Dr. Theodor Peckolt, of Rio Janeiro. As far as we know, none has yet been received in a condition suitable for use. Dr. Peckolt has obtained from the juice a white, amorphous substance, which he calls *papayotin*, and which, it appears, is a sort of vegetable pepsine. It will probably be produced at a reasonable price in Brazil, where the tree is very common. The fruit is not much used, except by the Indians, but it would be very valuable in medicine if the milky juice could be more easily obtained. This juice is found in all parts of the plant, but only the unripe fruit contains considerable quantities, and it disappears during ripening. It is very troublesome to collect, even from the unripe fruit. In the colder months it is extremely scanty, and only from August to April can it be obtained in somewhat more profitable quantities by slitting the fruit while it still hangs on the tree, when the milk exudes in drops. If the fruits are taken from the tree, at most only a few drops can be obtained, and these coagulate in the gashes. From a medium-sized fruit, weighing 785 grams, Dr. Peckolt obtained 33 grams of juice. Thirty fruits had to be treated to obtain a kilogram of the juice, and in these the incisions had to be repeatedly renewed, as the juice soon coagulates in them. This collection, from trees fifteen or twenty feet high, is evidently a very troublesome and unprofitable task.

Treatment of Nævi Materni by Linear Scarifications.

M. Vidal, of the St. Louis Hospital for Skin Diseases (Paris), operates in the following manner (*Thèse Colson*), using a small needle with a triangular point:—

Local anæsthesia is produced with ether by Richardson's atomizer; then, with the needle, M. Vidal makes straight incisions parallel with each other, about one-twentieth of an inch in depth, and about as far apart, so that small sections of the skin, about one-twentieth of an inch square, are formed.

The first effect of the incisions is abundant hemorrhage, much less marked if the skin is well stretched while the incisions are being made.

When the operation is finished, blotting paper will prove sufficiently hemostatic, and by absorbing the blood from between the incisions removes any obstacle to reunion by first intention. The lines of scarification remain visible for two or three days, but after a week union has taken place. Scarifications should thus be made each week; after about six weeks the color is modified by real amelioration, comes slowly a violet-colored nævus, becoming wine red, then a brownish red, and finally rose-colored.

For a rose-colored nævus fifteen or twenty scarifications are necessary; in the end, the skin appears without visible cicatrix; and this is one of the principal advantages claimed for M. Vidal's method.

The Over-feeding of Infants.

Dr. Taaffe, the Medical Officer of Health of Brighton, England, referring to the extreme proportion of deaths of infants from diarrhœa (91 per cent. of the total deaths from that cause being deaths of children under five years of age), said there was evidence that improper feeding and improper nursing, even where the mothers themselves nursed their children, were the principal causes of such infantile mortality. Not only was the kind of food injurious, but from experience in the children's hospital he knew that most, if not all, infants had food given them from hour to hour. Such gross feeding would not be survived by an adult for more than a few days, and the injury to infants might be imagined. He added: "until the poorer people are better instructed how to feed their children the mortality from diarrhœa will always be great." He might have added that the richer people, too, would be the better for more sanitary information.

Fly Dirt as a Local Remedy.

We have learned that cockroaches are "good for dropsy." And now we are informed, in the Calcutta *Medical News*, that Babu Nabin Chandra Datta, assistant surgeon, Sitapore, Oudh, says he has tried the excreta of the common house fly in a number of cases of tinea decalvans, where hair has fallen off in one or two circular spots, with the most satisfactory result. The article in question can be obtained and used in the following way: Suspend a string of cotton thread in any fly-infested part of the house. At night it will be the resting-place of thousands of flies, and will, in consequence, be loaded with their excreta, which can be seen as numerous little black dots all round the string in the morning. Put the string into a small quantity of water in a clean glass, for a little while, when the excreta will be dissolved. This solution, rubbed over the affected part twice a day, will bring up a crop of hairs, in the majority of cases, in a fortnight or so.

This is going back to the ancient "*Dreckapotheke.*"

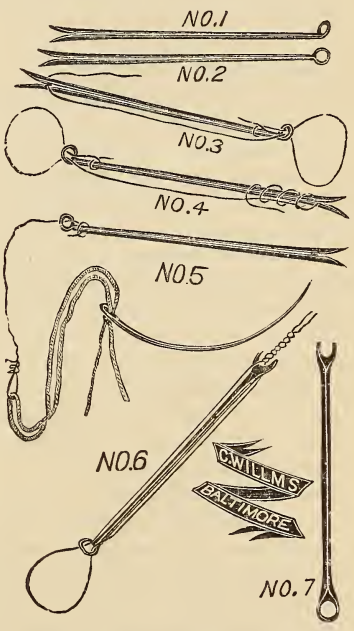
It is a dubious question whether, even if the above is intended as a serious statement, the natural disgust to such a remedy will not prohibit its use.

Special Reports.

III.—GYNÆCOLOGY.

Improvements in Perineoraphy.

Operators on the perineum always experience much difficulty in the removal of sutures applied to the recto-vaginal septum. Some employ catgut and leave it to be absorbed, but Dr. A. F. Erich, of Baltimore, has devised a stylet which meets the difficulty very well. He described it in the Maryland *Medical Journal*, of last September. Its use will readily be understood from the following cut and description:—



ERICH'S DEEP SUTURE STYLET.

The stylet is of steel and 1½ inches long; at one end is an eyelet, and at the other a small, rounded fork. (See cut, No. 7). Both ends of the wire are passed through the eyelet after they emerge from the tissues; carried over the fork at the other end, and twisted until the necessary tension is secured (No. 6). In some the eyelet is parallel to the shaft and in others, at right angles to it. In some cases the sutures are most easily secured by the stylet figured in No. 1 and 2. Here one end of the wire, after passing through the eyelet, is secured to the shaft by a single twist (No. 5), and the other after being tightened by traction with a gentle pendulum motion is fastened temporarily by passing over the clamping fork at the upper end of the shaft (No. 3). It can then be permanently secured by a few turns around the shaft. (See No. 4.) After the sutures are all secured the stylets are brought together and a piece of gum tubing slipped over them.

Esthiomenos Ano-vulvaris.

This local affection will not be found mentioned in the text-books of Emmet, Thomas or Goodell; but it is referred to in Huguier, and recently has been fully described by Professor Martineau, in a series of articles running through the *Gazette des Hôpitaux*. It is a scrofulous and tuberculous affection, not very rare, and often confounded with lupus, lepra and similar diseases. There are three leading types: 1. Superficial inflammation, of a serpiginous character, attacking the superficies and not descending below the dermis. 2. Perforating inflammation, extending more deeply. 3. Hypertrophic inflammation, somewhat of the character of elephantiasis.

The disease is slow in its progress and obstinate to treatment. It is distinguished from elephantiasis, as this latter presents a hypertrophied skin in its early phases, and is without any tubercles. In lepra the tubercles are flattened, dark in color and painless; in esthiomenos they are sensitive, more prominent, and reddish-yellow in color. Cancer of the vulva, whether schirrhous or encephaloid, attacks the subcutaneous tissues first and the skin only subsequently; with esthiomenos this history is reversed. From syphilitic ulcerations it is distinguished by its reddish color, by the neighboring skin being implicated, and by the absence of general syphilitic symptoms.

The treatment is a general, constitutional one, for scrofula, and a local one, which embraces cleanliness, astringents, bromide of potash, to reduce the itching, local use of lime-water, aromatic wine, Labarraque's solution, solutions of iodine or carbolic acid, iodoform in powder, etc. Caustics, as Vienna paste or chloride of zinc, are called for in severe cases; and as a last resort, the extirpation of the whole diseased part by the knife has given good results.

Normal and Abnormal Menstruation.

A Moscow physician, Dr. Bensenger, has found, from a series of 5611 women in Moscow and the surrounding province, that the first menstruation, on the average, began at the age of fourteen years, eight months and fifteen days. Among the upper classes it generally appeared earlier than among the lower classes. This, in the opinion of Dr. Bensenger, results partly from their more favorable hygienic condition, and partly from their superior intellectual activity. Menstruation ended between the forty third and forty-eighth years. The average number of years during which menstruation persisted was thirty-two.

It is not altogether rare for the menstrual flow to reappear after it has for years been absent. At a meeting of the Cambridge, England, Medical Society, last summer, Dr. Paget recited two instances, as follows:—

Case 1.—A married woman, 65 years old, had a sanguineous uterine discharge for three weeks before she presented herself; it had been brought on, she said, by the return of her son from abroad. In the absence of any other assignable cause, there could be no doubt that this emotion attending her son's return was really the exciting cause. He was her only surviving child, he was in prosperous circumstances, and his return had been eagerly expected. Fifteen years had elapsed since her last menstruation The discharge soon ceased under treatment with iron.

Case 2.—The second patient, aged 60, lost her husband, and soon after her daughter, who died suddenly, in childbed. Her mental distress was very great; her mind became disordered; simultaneously menorrhagia came on, and she had also a delusion that there was a baby in the bed. The catamenia had ceased naturally many years before.

In these, as in most such cases, there would be no likelihood of confusing these discharges with the catamenia.

Irritable Bladder in the Female.

While a large variety of causes give rise to vesical irritability in women, Dr. Oppenheimer (Louisville *Medical News*, June, 1880,) directs especial attention to two—*constipation* and *urethral inflammation*. The habit of constipation is very common among women, partly, as Dr. Goodell has judiciously pointed out, owing to faulty closet accommodations, and it should be made a subject of inquiry in such cases.

When the cause can be traced to a urethritis, specific or otherwise, the regular treatment of the Louisville city hospital is to apply the following, on a piece of cotton:—

℞. Chloral hydratis,
Acidi carbolici,
Potassii iodidi, āā. gr. j
Aquæ, f. ℥ j. M.
Sig.—To be used locally.

It causes a slight burning sensation at first, which soon disappears.

Correspondence.

Position in Labor.

Ed. Med. and Surg. Reporter:—

In a recent paper in the Reporter, I mentioned the kneeling position as an unfavorable one to the parturient, in that while she was unable to take any rest during her labor, she was not in a condition at its close to be placed immediately in bed, as she so often imperatively

demands. I did but glance at the undesirableness of the method, not expecting that it would find either advocate or apologist. Your correspondent at Atlantic city, having very courteously presented some views which seem to him to make the plan preferable in some cases, it may not be amiss that I state my objections somewhat more in detail.

My observations relate to country practice, where alone, I presume, this method is followed. The conditions here intensify the objection. The houses, standing alone, and often in the bleakest places, are mostly built of frame, with clapboards and lath and plaster walls. The floors are often imperfect, and admit draughts of air. The heating is universally by stoves, which fail to warm the floors. If, then, the parturient kneel by a chair upon a quilt, as is the custom, her feet and legs become icy-cold, as I have frequently observed, even when the upper part of the body, from the muscular effort, was preternaturally warm. When the bag of waters bursts, the evaporation from the surface of the constantly wetted extremities very much increases the discomfort. With the cessation of exertion, at the close of the second stage, the patient feels cold, and would like to be tucked nicely in bed. She may be imperfectly covered by a quilt; but the placenta is yet to be delivered, and that may be very difficult, as I have found it on many occasions so firmly adherent, and by so large a surface, that I have been obliged to introduce the hand and patiently separate the adhering structures. I do not think I should like to attempt this in the position named. The placenta delivered, it is necessary to secure and maintain uterine contraction; to apply the binder; to dress the mother and place her in bed. It is not possible to properly apply the binder while the patient kneels; and while robing, I have known such alarming hemorrhage to come on as to make it necessary to grasp the womb and enforce contraction, while the patient was being lifted in bed. Besides, the napkin placed at the vulva to receive the lochia is mostly displaced during this shifting process, and the patient's bed is soiled before she is fairly in it. Moreover, she may swoon, as I have known, even when in the recumbent posture.

Whatever force there may be in the claim that the weight of the child coöperates with the muscular efforts in effecting delivery, it is fortunate that its influence is lost the moment the pain ceases; and that the presenting part recedes from the constriction, thus allowing the strained and fretted parts a period of repose. It is well to remember, too, that the kneeling position does not tend to bring into line with the axis of the superior strait the muscular forces which are the great agents of delivery.

I condemned this position as very wearisome and awkward to the practitioner. He cannot well assist his patient except he kneel behind her, a juxtaposition of little dignity, and one apt to involve the soiling of his clothing. In employing the touch, he is obliged to bend his wrist in a very uncomfortable way, especially if the os uteri be high up on the sacrum. Should the anterior lip become engaged between the pelvis and the head of the child, impeding its descent, as so often happens, he is obliged, in order to reach the impacted part and cause it to recede over the parietal protuberances, to submit to a position of the wrist still more constrained and irksome. The difficulties are greatly increased should the patient, as she is apt to do, bring the os externum close to the pallet on which she kneels. Supporting the perineum is also a most unsatisfactory proceeding; while the possibility of disposing of the involuntary discharges from the rectum in such a way as to be reconcilable with one's ideas of decency and delicacy is greatly diminished.

It may not be uninteresting to state that, between the writing of my communication and its publication, a lady who I had many years since delivered of her first child in the usual position, and who afterwards had given birth to a large family, called me to attend her, declaring that she could not be delivered in bed. Notwithstanding my accession to her wish to kneel, and that the infant weighed quite twelve pounds, the labor was protracted, involving many of the discomforts mentioned, so that my position as accoucheur was anything but a sinecure. * * *

Having been much "about cattle" in my youth, I cannot indorse the proposition that the kneeling posture is *secundum naturam*. Coming not infrequently upon the domestic animals during parturition, I invariably found the cows, in the final stage, lying upon the side, with the forelegs folded under the chest and the hinder ones stretched out so as to allow the abdominal muscles free motion. My observation among mares extends to only a few cases; but, so far as I observed, they assumed the same position.

E. T. Blackwell, M.D.

Hackettstown, N. J.

Scarlatinoid.

Ed. Med. and Surg. Reporter:—

There is at this time prevailing here a disease somewhat resembling both scarlet fever and diphtheria. On the first, second or third day a scarlet rash makes its appearance on a part and sometimes over the whole surface of the body, which generally soon disappears or loses its brightness, but is discernible in the skin for several days. Sore throat and swollen lymphatic glands invariably attend, and in bad cases considerable tumefaction occurs about the throat and side of the neck. In all the cases the diphtheritic deposit is more or less present and sometimes very persistent. The papilla of the tongue may or may not be raised, and in no case is this index at all comparable with the scarlatina anginosa of thirty-five or forty years ago. Fever and heat of the body is at no time great, and thirst, when it exists, is only moderate. The relaxed uvula and greatly swollen tonsils, in the worst cases, very soon render the breathing audible, and during sleep the patient must often be aroused, to prevent apparent suffocation. In one case there was lividity of the face, followed by convulsions, on the fifth day. The patient a boy seven years old.

From the fourth to the seventh day a change generally occurs, followed by a copious flow of

mucus and ropy lymph from the mouth and nostrils; after which convalescence occurs.

All cases have thus far recovered under the same treatment which I have relied on for several years in diphtheria. On call this evening, for a boy aged eight years, I prescribed:—

℞.	Chlorine water,	f. ℥ iij	
	Sulpho-carbolate of soda,	℥ ss	
	Glycerine,	f. ℥ iss	
	Water, q. s., ad	f. ℥ vj.	M.

Sig.—A teaspoonful in two teaspoonfuls of well sweetened water, every two hours.

And melted lard, saturated with gum camphor, to be applied externally to the swollen glands.

Whatever else may seem to be indicated, the above prescription, suitably modified to age and condition, is given in all cases until restoration is evident.

Stillé and Maisch, in their National Dispensatory, 2d edition, I think, do not mention the sulpho-carbolates, and certainly speak most disparagingly of the internal use of chlorine water in this and all kindred diseases.

I have never found any preparation so reliable, effectual, and safe, as the above compound, when well followed up, in diphtheria. My fatal list is almost absolutely *nil*, during four or five years, last past, with certainly quite a number of grave cases to note.

The chlorine water should be pure, and the dose may vary from fifteen minims to half an ounce. The prescription will be found to be elegant, and acceptable to the patient, especially if sugar and more water is added.

I am gratified to learn from correspondents who are readers of the Reporter, that lime steaming (not lime water) in diphtheritic croup is being tried more generally. About nine out of every ten well marked cases will perish without it, while I believe, from experience, that a great majority could be saved, if early and properly used, in connection with thorough antiseptic and supporting treatment.

George Hill, m.d.

Hughesville, Pa., Dec. 22d, 1880.

Medical Confessions—Incompetence in a Brow Case.

Ed. Med. and Surg. Reporter:—

I am much pleased that you have opened a column for confessions, where erring brethren can free their minds. The first case that comes to my recollection, is one where, from incompetence, I feel that I may have been instrumental in delaying a case of labor, and possibly, sacrificing the child. I saw a multiparous woman in labor, and felt no alarm, as the head was presenting. For an indefinite time it continued presenting, and I then proposed to deliver with forceps, but I did not deliver. Something held it. After I was exhausted I sent for a medical friend, who was an adept, but he gave it up, after being exhausted. Eventually I passed my hand above the head and found that the face was anterior. I changed it without difficulty and then readily delivered a dead child. I am pretty certain that I have never been caught in the same way since that time, and strange to say, more than an average number of brow cases have fallen to my share.

I do not have much confidence in the man who can place his finger in the vagina and make out the position. He may think he can, and as the majority of vertex cases are left anterior, he may find that nature may aid him in his diagnosis.

My practice now, is to let a vertex case run on, and if the head comes down quickly, do nothing. If, however, there is no advance of the head, I introduce the hand and render the position of the head known to a certainty. If it is a brow case, I seize the head with my hand and push up steadily till I can turn it right about, and hold it that way for a time, till the body of the child assumes its proper relation. I find that it may take two or three attempts before the head can be brought down in its proper position, for the occiput shows a peculiar tendency to turn backward.

If I had met a confession similar to the above, I am certain that my first brow case, as well as her medical attendant, would have been saved much annoyance, to say nothing of graver issues.

Alpha.

News and Miscellany.

The Value of Boards of Health.

Already New York is reaping advantages from the recently created Board of Health.

It is worth while giving some particulars of the effect it has had in limiting smallpox. From statements made by the Secretary, Dr. Elisha Harris, who is also Superintendent of Registration, an account of the spread of smallpox in Rensselaer, Washington, and Fulton Counties is gathered, which will give an idea of the importance of State supervision in sanitary regulations. Little excitement has gone abroad about the prevalence of smallpox in the counties named, but in from twelve to fifteen towns the alarm has been very great, and there has arisen a great desire to apply vaccination and other methods of prevention as soon as possible.

In July last smallpox appeared in Troy, among some French Canadians who were not vaccinated, and who had come to Troy to obtain employment. It spread with rapidity, as the people among whom it originated or developed were averse to vaccination, and careless about their movements, even when the pustules were upon them. It was some time before the public health authorities heard of the outbreak. As soon as they did they looked for traces of the origin of the disease, and became satisfied of its Canadian beginnings. An attempt was made to confine the disease to the spots in which it had first appeared, and reports were made from week to week, by the local board, of the work of vaccination that had been done. Although not entirely successful this was so in great measure.

In Troy and Cohoes the disease has been very fatal. About one-half of the unvaccinated persons attacked died. So far as ascertained not one vaccinated person has died. Persons who were vaccinated after exposure, and who met the smallpox half way, even after pustules

had appeared, have been reported as recovering.

In the not less fatal disease of diphtheria the Board has also been active. A striking instance of its malignancy is given.

The attention of Dr. Elisha Harris, the Secretary of the State Board of Health, was directed, last summer, to a centre of the disease in Johnstown, Fulton County, and by great diligence the shanty of a family was found to be the starting point from which it had gone abroad until it had found victims in every part of the village, and afterward found its way far up toward the north woods. In the shanty referred to two children had been stricken with diphtheria, and died. A family from a distance made a visit to the house, and the children who were among the visitors slept in the very same bed in which the children had died a short time before. They went home, and soon after had an attack of diphtheria. An infant who had sickened and died in the neighborhood was carried in its mother's arms forty miles east, across country, two other children riding in the same conveyance. They carried the disease with them, and it crept along south again, until it reached Northville. The first fatal case here was that of an admired child, and, in gross ignorance of the fearful danger to which the neighborhood was exposed, a public funeral was held in a church; the corpse was carried in by child bearers, companions of the dead one; the church was crowded, principally with children; a sermon was preached, and the body was followed to the grave by a long concourse of people, young and old. The result was one that should not have surprised anybody. The funeral infected the whole village, and in a week there were forty-six cases of diphtheria in the place. The Board of Health was alarmed at this and other instances of carelessness, and while Dr. Harris was in the neighborhood investigating the matter, he sat down one day and wrote a circular, which has been distributed far and wide, giving tersely all the particulars as to the infectious nature of the disease, pointing out the necessity for isolation of patients, cleansing and disinfection of rooms and clothing, and emphatically directing that funerals shall be private.

Diphtheria in Illinois.

It appears that during the past year the town of Morris, Illinois, has been terribly ravaged by diphtheria. A few days ago a correspondent of the Chicago *Times* gave an account of the matter, from which the following particulars have been taken. The population of the place is about 4000; yet, out of a total of two hundred and seventeen deaths in the past nine months, one hundred and fifteen have been caused by diphtheria. In one cemetery there have been ninety-seven burials since January last. The disease prevailed as an epidemic, and was so terrible in its effects that the public schools were closed, and many citizens left town. The Catholic priest is said to have buried twenty-three children in one week. At first one-half the cases that appeared proved fatal.

Items.

—Dr. Herman Bush, a well-known physician of California, died in San Francisco last month, aged seventy-six years.

—The Botanical Department of the Cornell University has recently received a donation of $10,000, from Hon. H. W. Sage, of Ithaca, N.Y.

—Dr. Wm. Pepper has been elected Provost of the University of Pennsylvania, and has accepted the position. The choice of a person for this responsible position could not have been made more judiciously.

—The United States Consul, at Surinam, Guiana, gives some strange statistics from that colony. The deaths are constantly in excess of the births, and the children born out of wedlock are about four times as numerous as those which are legitimate!!

—Dr. Salvador Badia, in *El Genio-Medico Quirurgico*, states that it is calculated that about 22,000 persons visit the baths of Luchon (Pyrenees), annually, of whom from 4000 to 5000 take the baths. These visitors leave behind them during the short season (July to October) from eight to nine millions of francs.

—The Registrar of Vital Statistics of New York city has presented a report to the Board of Health, embodying the startling statement that during the past year there were no fewer than 3894 deaths from zymotic diseases, influenced or aggravated by defective plumbing allowing sewer gas to enter the sleeping apartments of the victims.

—There is considerable smallpox through northern Mexico. At Matamoros it is at present an epidemic. Other diseases also prevail. The deaths from all causes during the five weeks ending Dec. 4th, 1880, were 109, giving the enormous annual death-rate of 71 per 1000. Even this rate is, no doubt, too low, as probably 25 per cent. of deaths are not reported, and the estimated population of 16,000 is supposed by the Consul to be too high by one thousand. Smallpox is chiefly confined to the poorer classes of natives, and to children, most adults of that class having had the disease. Their prejudice against vaccination precludes any effectual measures of prevention. Only one foreigner is known to have taken the disease this season, and the exemption of strangers and of the bettter class of natives is remarkable, considering the frequent exposure to contagion which they must encounter in all public places.

OBITUARY NOTICES.

Ford.—Dr. George Ford, who has for over thirty years been connected with the State Emigrant Refuge and Hospital, on Ward's Island, New York City, died at his residence, on the island, January 7th, of gastritis. Dr. Ford was born in County Leitrim, Ireland, in 1812. He graduated from the Royal College of Surgeons in London, in 1837, and came to this country in 1849. He received the honorary degree of Doctor of Medicine from the old New York Medical

College. Dr. Ford was a member of the County Medical Society and of the Pathological Society, as well as of the Society for the Relief of the Widows and Orphans of Medical Men, and of the Friendly Sons of St. Patrick. He was a man of very retired habits, attending strictly and conscientiously to the duties of his office, to which he gave his whole time.

VATTIER.—Dr. J. L. Vattier, the last of the celebrated Seven Men's Society, died in Cincinnati on January 13th. The Society was formed nearly fifty years ago, between seven prominent citizens. They agreed to meet once a year, for a social dinner, so long as they lived. At the annual banquet the empty chairs of the dead were to be placed at the table, and dinner provided as usual, for the full number. A bottle of wine was locked in a mahogany casket and the key thrown away, with the agreement that the last living member should break the lock and drink the wine after the death of all the others. Dr. Vattier, the last survivor, broke the lock, and drank the wine, and has since annually sat down alone to a dinner for seven, the six empty chairs being still at the table, in remembrance of his six dead companions.

QUERIES AND REPLIES.

High Temperature.

MR. EDITOR:—Permit me to ask a question. Is the temperature of a patient always a criterion of fever, and does high temperature signify anything serious with the patient? I ask because of doubt in my mind, and refer to the following cases: A patient convalescing from a protracted illness, consequent on subinvolution of the uterus after confinement; the thermometer in her axilla to day registered 104°, apparently without any increase of fever or any untoward symptom. There was some mental excitement just previous to the test. Another patient, last summer, convalescing from acute dysentery; the thermometer, during my visit, registered very high, without any apparent cause. The thermometer was not used again in this case, because of the alarm to her friends consequent upon the high temperature. Convalescence proceeded without interruption. I. S. C.

Ans.—A very high temperature may be registered without any fever present. The highest recorded temperatures have been in nervous diseases, where febrile symptoms were absent. See REPORTER, November 6th, 1880, p. 413.

Spaying of Women.

MR. EDITOR:—Is it true, that all, or nearly all Chinese women now living in this country have undergone an operation for normal ovariotomy previous to leaving China? Is it a custom among the Chinese in their own country to perform such an operation upon their women; if so, at what age; and what is the mortality resulting from the operation? Will you, or some others, please answer? B. R. F.

Pennsylvania.

Ans.—We have heard the statement, but believe it an error.

Psoriasis.

MR. EDITOR:—Will you, or some of the many readers of your valuable REPORTER, give me some light on a case of what appears to me to be well-marked psoriasis of the penis, involving nearly the entire organ? It is of about nine months' standing. Nearly all of the standard remedies have been used, but all without effect as relates to a permanent cure. R. C. G.

EDITOR REPORTER:—The wife of a neighboring physician has been ill for some time. The principal difficulty is a pelvic tumor, probably a degenerated ovary, and ascites. There is some difference of opinion among the physicians who have examined her, as to whether the growth is malignant or not. Those who hold most tenaciously to the opinion that it is malignant, base their opinion principally upon the rapid growth and nodulated feel of the tumor. *Query.*—Is nodulation a pathognomonic symptom and positive evidence of malignancy. E. Y. N.

Ans.—Nodulation increases the probability of malignancy, but it cannot be regarded as a strictly pathognomonic sign, inasmuch as it occurs in certain benign tumors.

Dr. C. F. McB., Pa.—Pilocarpin costs thirty-five cents a grain. Chrysophanic acid costs about $1.00 per ounce. Both can be had of any first-class drug house in Philadelphia or New York.

MARRIAGES.

BLUMENTHAL—LOTTIMER.—In New York, on Thursday morning, December 16th, 1880, by the Rev. Charles C. Tiffany, of Zion P. E. Church, Charles E. Blumenthal, M.D., and Mrs. Jane C. Lottimer.

LONG—WINSLOW.—In this city, on the 6th instant, at the house of William C. Carrick, No. 1919 Vine street, by the Rev. N. J. Rubinkam, Howard Long, M.D., and Clara Winslow, daughter of Stephen N. Winslow, of Philadelphia.

REYNOLDS—MYERS.—November 25th, 1880, by the Rev. W. F. Hamilton, J. M. C. Reynolds, M.D., and Miss E. Elma Myers, both of South Strabane, Washington Co., Pa.

SIMPSON—EASLER.—In this city, on Monday, December 27th, 1880, by the Rev. J. M. P. Otts, D.D., Robert Simpson, M.D., and Alice, eldest daughter of the late John Easler, both of Philadelphia.

TIBBETS—MOCKBY.—In Cincinnati, Ohio, on Thursday evening, December 23d, 1880, by the Rev. J. S. Whitney, Earl Tibbets, M.D., of this city, and Miss M. Mockby, of New Richmond, Ohio.

DEATHS.

DORE.—Suddenly, at sea, on board of steamship City of Berlin, December 20th, 1880, Dr. David T. Dore, aged forty-one years, surgeon in the service of the Inman Steamship Company.

FORD.—At his residence, Ward's Island, George Ford, M.D., Physician-in-Chief of the State Emigrant Refuge and Hospital, of New York.

HOUGHTON.—In New York, on January 6th, 1881, Dr. Robert I Houghton, in the fifty-fifth year of his age.

HUDSON.—At Riverside, Conn., Friday, December 31st, 1880, of pleuro-pneumonia, Erasmus D. Hudson, M.D., of New York City, aged seventy-five years.

SAVILLE.—In New York, on January 11th, 1881, of pneumonia, Henry Martin Saville, M.D.

SELLERS.—In this city, on the 5th inst., Hiram F. Sellers, M.D., aged forty-five years.

TAYLOR.—In this city, suddenly, on the morning of January 3d, 1881, of apoplexy, William J. Taylor, M.D., formerly of Hunterdon county, N.J.

TODD.—December 14th, 1880, Ostrander D. Todd, M.D., of Allenport, Pa., in the seventy-first year of his age.

WELLS.—Surgeon C. P. S. Wells, United States Navy, died at the Washington Navy yard, January 1st.

Agents for Barlett's Pile Suppositories.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

CHLORAL HYDRATE AS AN ANTIDOTE TO STRYCHNIA.

BY H. H. KANE, M.D.,
Of New York City.

Liebreich was the first to demonstrate the physiological antagonism existing between chloral hydrate and strychnia, more especially the power of the former to save life in cases of poisoning by the latter. The power of strychnia to antidote the poisonous effects of chloral was also considered, but is by no means so well proven as the influence of chloral in strychnia poisoning.*

Since then chloral has been used as an antidote in a number of cases of strychnia poisoning. C. M. Worthington † reports one case where chloral was successfully used. Another is reported to me, by letter, by Dr. F. Delmont, of San Buena Ventura, Cal.

The following interesting case is reported by Dr. George Gray, in the *British Med. Journal*:‡

On December 30th, 1879, I was called upon to visit a man living about two miles and a half distant, who, the messenger informed me, had taken a poisonous dose of strychnia. When I arrived at the house, about half-past twelve o'clock, I found the patient, a man of 34 or 35 years of age, supported in bed in a semi-recumbent position, with his head thrown back, his eyes staring, and evidently suffering from the usual symptoms of poisoning by strychnia. The muscular spasm came on with a tremor like a jerky kind of convulsion, and recurred about every three minutes. During the spasm the breathing was irregular, and the breath came through the closely-clenched teeth with a hissing sound. The angles of the mouth were drawn down, and the peculiar Sardonic grin well marked; the skin was cold, and covered with a clammy perspiration. The pulse was very weak and quick, but not irregular. During the intervals between the convulsive attacks the spasm of the jaw did not pass off, and any attempt to open the mouth forcibly at once brought on a fresh attack, which was preceded by a peculiar sound—half groan, half cry.

Having brought with me a solution of two drachms of hydrate of chloral in two ounces of water, I poured half of it into a cup, and managed slowly to administer it with a teaspoon by inserting the point of the latter in a space where he had lost two molar teeth, and directed him to suck in the fluid. This he did in the intervals of the attacks, swallowing it with a gulp until the ounce of fluid was taken. After swallowing the chloral, he had only two severe spasms, the latter less marked than the former; and at gradually lengthening intervals they became less severe. In ten minutes the jaw so relaxed that I thought I could introduce the tube of a stomach-pump, but as doing so seemed to cause great distress, and increased the jerking of the muscles, I did not persevere, but gave him an emetic of thirty grains of sulphate of zinc and warm water,

* "Ueber das Strychnia als Antidot bei Chloral-Vergiftung," vorgelegt von Herrn du Bois-Reymond, in der *Gesammtsitzung der Königl. Acad.* der Wissensch. zu Berlin, 9 Dec., 1869. "Strychnia als Antidot bei Chloral-Vergiftung." Ber. d. deutsch-chem. Ges., 1869, p. 673. "La strychnine comme antidote du chloral." *Compte Rendu* de l'Acad. des Sciences. 1870. t, 70 p. 403.

† *Pacific Med. and Surg. Jour.*, Aug., 1879.

‡ *Medical Gazette*, April 24, 1880.

and when this had acted, I gave him a drachm of tannin; this he vomited also.

After waiting for an hour, as there were now and then slight tremors in some of the muscles, as no doubt some of the chloral was removed by the emetic, and as there was not any drowsiness, I gave half what remained of the solution—that is, half a drachm of chloral-hydrate. and applied warmth to the skin. In another hour he was so much improved that I left, giving directions that if he had any more twitching, or if he had not any drowsiness—which had not yet appeared—to give him in three hours the remainder of the draught, and to let me hear of him in the evening. At *seven* o'clock I heard that he had the chloral draught at *five*, but had not slept, and was feeling comfortable, having no more vomiting or convulsions. I ordered him a dose of castor-oil at bedtime.

There is nothing further to note of the progress of the case, as two days afterwards he was at his usual work.

On making inquiry I found that for a fortnight before he had been drinking constantly, and was in bad spirits about losing his situation, and that about half-past ten on that morning he purchased some strychnia, ostensibly to poison rats. He then went into a public house, ordered a glass of whisky, stirred in the strychnia, and at once drank it off, adding water to the tumbler to suspend a few crystals that remained, and swallowed these as well, so that both the man who was with him and the patient assured me had taken all he purchased, which was sold to him for twenty grains. After taking the poison, he told his friend it was a powder he had bought to "put his stomach into good order." He then felt sick, went out into the yard of the public house and vomited, got on a car which was waiting for him, and drove home, where he announced what he had done. His friend at once melted a pound of butter and made him swallow it, and sent for me. As well as I can make out, the symptoms came on about an hour after he took the poison, and had continued about an hour when I saw him.

I have thought the case worth bringing forward, on account of the large dose of the strychnia, and also as showing well the antagonism between chloral-hydrate and strychnia, and the great value of the former as an antidote in poisoning by the latter. Although some of the chloral must have been lost when the patient first vomited, enough was given afterward to produce profound sleep in an ordinary man, and yet the physiological action of the drug was not manifested in the slightest degree, but seemed to be neutralized by the action of the strychnia. Living as I do in the vicinity of several demesnes, which are strictly preserved, and in which poison has been sometimes laid for vermin, I have frequent opportunities of administering chloral-hydrate to dogs which have accidentally picked up strychnia; and out of the number I have been able to save five. This is the first time I have had an opportunity of testing the value of the antidote in the human subject, and from the marked and immediate relief it afforded, I can speak very highly of its value. With regard to the enormous quantity taken, two things at once suggest themselves; was it all taken? And if so, was it pure strychnia? Both the patient and his friend affirm that he was most particular in washing every crystal out of the tumbler, with water which he swallowed, and that he must have taken it all. As to the purity, I applied the rough tests given for the purity of the alkaloid in the Materia Medica, and according to these it was pure. This, however, did not satisfy me; so having obtained from the same person a like quantity, out of the same bottle, through the kindness of Professor Cuming, I had it analyzed, and I think I cannot do better than read for you what Dr. Lefts, Professor of Chemistry, Queen's College, Belfast, says of it. "I have carefully examined the strychnia. Its weight amounted to 1.554 grams, that is, over 22 grains. That such a quantity, could have been taken without a fatal result is almost inconceivable, and I was much inclined to believe that the sample was largely mixed with some cheap alkaloid or with mineral matters. I have tested for brucine, quinine and mineral matters, but can find none. I have also made a quantitative analysis. Strychnia gives an insoluble chloroplatinate, and the chloroplatinate contains 18.3 per cent. of platinum. If the sample of strychnia you gave me consisted of pure alkaloid, 0.315 parts ought to give 0.510 of the chloroplatinate, instead of which, I got 0.462; the slight deficiency being due, probably, to the fact that the chloroplatinate is not absolutely insoluble in water, and thus some remained in solution. If we calculate from the weight of chloroplatinate found that of the pure strychnia taken, the result is 96.4 per cent. of the sample actually taken. In other words, the sample you gave me contains at least 96.4 per cent. of pure strychnia. To be quite certain that the salt which I obtained by dissolving the sample in hydrochloric acid and adding chloride of platinum was really the chloroplatinate of strychnia, I determined the platinum in it. It amounted to 18.3 per cent., whereas the calculated percentage of platinum is 18.3.

There cannot be the slightest doubt, therefore, that the sample of strychnia you gave me consists almost entirely of pure strychnia."

Now, that a man could take 22 grains of strychnia and afterward recover, is remarkable, and I think we can only attribute the result to a combination of circumstances. He had been drinking for some time, and his stomach was in an irritated state, which retarded absorption of the poison. The strychnia, being taken in crystals, was not dissolved for some time. The vomiting, in this instance, enabled him to get rid of some of it. The butter which his friend gave him further helped to delay the advent of the symptoms, but, notwithstanding all these, enough strychnia remained to produce very severe symptoms of poisoning; and I feel certain that the good ending of the case was owing chiefly to the action of the hydrate of chloral.

Professor Huseman,* of Göttingen, has been engaged in a long series of observations on the antagonistic and antidotal actions of drugs, and some of his investigations which relate especially to chloral are described in a recent number of the *Archiv für Experm. Pathologie.* Of these the following is a summary: Chloral hydrate is known to act as an antidote to strychnine, lessening the spasm, and even preventing death. It has a similar action in the case of the mixture of strychnine bases sold under the name of brucin, and also against the opium alkaloid thebaia, which simultaneously tetanizes and lessens sensibility. The spasms produced by chloride of ammonium diminish under the employment of non-fatal doses of choral hydrate, and can, indeed, be completely stopped. Nevertheless death occurs, probably from the paralyzing effect of both substances on the respiratory centre. The antidotal effect of chloral on the action of the poisons which cause convulsions by their action on the brain is not the same for all these substances. The quantity of the poison which can be counteracted by the antidote appears to be considerably greater in the case of picrotoxin than in the case of codeia. Of the latter, indeed, the fatal dose, and even a quantity half as much greater, can be rendered harmless, but twice the fatal dose cannot be counteracted, and is still fatal. Calabarin is counteracted by chloral hydrate in about the same degree as codeia. The symptoms produced in rabbits by poisoning with baryta are not materially altered by the action of chloral, which does not appear to prolong life. So, also, with carbolic acid; the spasms produced by it are not arrested by chloral, and the minimum dose fatal to rabbits still produces death. The combination of a fatal dose of carbolic acid with a non-fatal dose of chloral hydrate causes in rabbits a remarkable fall of temperature, which is not produced by the action of these alone. As a rule, when chloral antagonizes the action of these cerebral poisons, the respiration sinks in frequency much more than in the case of the analogous action of chloral on the tetanizing poison. The depression of temperature caused by the chloral is almost independent of any peripheral loss of heat. The elevation of temperature, due to division of the spinal cord, is hindered by chloral hydrate. The depressing action of thebaia and codeia on the cerebrum, which is distinctly perceptible in many animals in addition to their action in causing spasm, is the chief effect recognizable in man. On the one hand, thebaia has a distinct action in lessening pain; and on the other, in human poisonings with this opium alkaloid, chloral hydrate is of little use, and in the case of poisoning by codeia, on account of the collapse which is produced, it is positively injurious.

Mr. Groves* relates the case of a dog poisoned by an unknown quantity of strychnia. where chloral rapidly caused a cessation of all bad symptoms.

At Mt. Sinai Hospital, this city, a man aged twenty seven years was being given, subcutaneously, one-fortieth of a grain strychnia, ter in die, for the relief of spinal difficulty. February 11th, 1877, at 11.10 A.M., he was by mistake given subcutaneously two-fifths of a grain of strychnia; at 11.45 violent convulsions. Was given fifty grains of chloral, subcutaneously, with the result of removing all spasm by 12.25 P.M. On the 24th of February he was again given one-third of a grain of strychnia subcutaneously. Convulsions again ensued. Again antidoted by fifty grains of chloral hydrate, subcutaneously, in divided doses. Very severe abscesses formed at the point of puncture.

Mr. J. Gilbert Candy† and W. S. Graves relate a series of experiments on animals, that afford evidence of the antidotal power of chloral over strychnia.

Dr. S. A. Turner, attending surgeon, Grand River Agency, D. T., records a case of poisoning by an unknown quantity of strychnia, given to an Indian by a jealous squaw. Spasms came on soon after partaking of poisoned food, of

* *Lancet*, March 15, 1879

* *Pharmaceut. Jour.* HALF-YEARLY COMPENDIUM. July, 1870.

†*Pharmaceutical Journal*, August 21st and 28th, 1875.

which he took but a mouthful. Intervals between spasms when first seen by doctor, some hours after, from thirty to sixty seconds. One hundred and five grains of chloral were given in divided doses in the course of three or four hours, after which no more spasms. Recovery.*

The following interesting case histories are sent me by Dr. Delmont, of San Buena Ventura, California:—

Case 1.—Mr. M., aged forty, while visiting friends, ate some watermelon on which strychnia had been put to destroy squirrels. An emetic had been administered before my arrival; the spasms were very severe; gave thirty grains chloral in syrup; kept the patient as quiet as possible; ordered the chloral repeated every two or three hours. He took one hundred and eighty grains chloral in all; perfect recovery took place; he went to his business next day. Could not ascertain the amount of strychnia taken.

Case 2.—Mr. K., aged fifty-five, took strychnia with suicidal intent; in this case no vomiting took place, owing to the obstinacy of the patient in refusing to submit to any treatment; gave him forty grains of chloral, (the spasms were frightful). After that dose the spasms were less severe; repeated the chloral in thirty minutes, when the spasms became very light; kept up with the chloral every few hours until morning; two days after the patient went home. In this case fourteen grains of strychnia were taken. One hundred and eighty grains of chloral were given.

Case 3.—Mr. F., aged forty-two, took strychnia with suicidal intent, a few doors from my office. As in the preceding case, he refused to take any antidote. I tried to use the stomach pump, but owing to the powerful strength of the patient and his obstinacy, could not make it work. Gave forty grains of chloral in syrup; the spasms stopped entirely within thirty minutes; kept giving chloral at intervals of two or three hours, for twelve hours; the patient made a good recovery. In this case seven grains of strychnia had been taken. The amount of chloral used was one hundred and sixty grains.

A most extraordinary case of recovery from strychnia poisoning, due to treatment by chloral hydrate, is reported in last week's *Lancet*, by Dr. Charteris,† Physician to the Royal Infirmary, Glasgow. On March 12th, a butcher of this city, in a despondent condition, bought from a chemist two sixpenny packets of Gibson's vermin killer. These contained two grains of strychnia in each. Then he adjourned to the parlor of a public house, bought some whisky, in which he dissolved the contents of the two packets, added some ginger ale and drank off the mixture. In order to make sure work of it, he bought another draught of ginger ale and drank it from the same glass, so as to dissolve any remnants of the poison; this was about 11.30 A.M. Then he walked across the street to a butcher's shop and asked to be allowed to sit down. A succession of tetanic fits ensued, and these seem to have continued for several hours. About 1 P. M. an emetic of hot water and sulphate of zinc was given, which, however, produced only partial vomiting. It was 3.30 P.M., when he was brought to the Royal Infirmary. He was in great agony; violent tetanic spasms followed each other in quick succession, increasing in severity. With great difficulty the stomach pump was passed, but only some sour, watery fluid was withdrawn. At 4.50 P.M. ten grains of chloral hydrate, in syrup, were administered; twenty minutes after the dose was repeated and at 5.30 twenty grains were given. Immediately afterward there was a severe and prolonged spasm, succeeded by a flaccid state of the muscular system, hurried respiration, quickened pulse and drooping eyelids, phenomena which indicate the effect of chloral. Three more doses, 10 grs. each, were administered between this and 9 P. M., the symptoms of poisoning subsiding. The patient was dieted on milk and rice, and in four days had completely recovered. He said if he wished to die again he would choose something other than Gibson's vermin killer. Dr. Charteris afterwards tried some experiments on rabbits, and found that the strychnine most decidedly checked the poisonous effect, though in one case, when a longer interval had been allowed to elapse between the poison and the antidote, the animal was paralyzed from the middle of the spine downward. It is stated, also, to account for the slowness of the action of the strychnine in the man's case, that he had previously taken a substantial breakfast of ham and eggs.

Dr. Wm. G. Wilson, of Shelbyville, Ill., sends me the following:—

On February 22d, 1879, about 11 P.M., I was called to visit a patient supposed to have intentionally swallowed poison. While making ready to attend to the call, I learned much of the following history of the patient from the messenger, a man:—

M. S., a woman about thirty-three years of age, of doubtful virtue, with whom he, the mes-

* *Medical and Surgical Reporter*, June 15th, 1872. *Practitioner*, 1874, p. 380.

† *Lancet*, April, 1875.

senger, had for some months been keeping company; that night, after eating a very light supper, at a late hour, she expressed in his presence a wish to die. He having ascertained that she possessed a bottle of poison, and fearing that she might do some mischief with it, undertook to hunt it up from among her effects; while doing so he noticed her take something into her mouth from a paper, and becoming alarmed started for me. I arrived at the house about forty-five minutes after the supposed poison had been swallowed. Found the patient, a tall, large-boned, not very muscular woman, sitting on a lounge, very restless, hands cold, pulse weak and accelerated, respiration hurried, pupils somewhat contracted, and reticent when questioned as to whether or not she had swallowed poison, but willing to take remedies.

As there was no certainty as to what poison, if any, had been taken, I at once gave her, in about two ounces of water, twenty grains of pulv. ipecac. She had just swallowed the dose when her whole muscular system was convulsed with a tremor or shudder, so very characteristic of strychnia poison, followed by slight emprosthotonos, her neck coming in contact with my head as I sat in front of her. I immediately dissolved in about two ounces of water what I judged to be, without weighing, twenty-five grains of chloral hydrate (and I frequently administered it so, also, after weighing), manufactured by E. Schering, of Berlin, and gave it to her. The dose was not entirely in the stomach when she had a second emprosthotonotic spasm, that threw her off of the lounge, and a portion of the chloral regurgitated, which she spat out on the floor; but there was no emesis, nor was there at any time. I now had her placed on the lounge, on her back, and two men were directed to hold her there, where she had a number, perhaps twenty or thirty, of those emprosthotonotic convulsions, the most violent of which would throw her against the foot of the lounge, together with those restraining her, when the latter were off their guard at the time of attack.

There remained great restlessness between the convulsive seizures, but I could not discover that there was loss of consciousness at any time. Ten minutes after the first dose I administered a second dose (twenty-five grains) of chloral. There appeared about this time great irritability of the bladder, for which she had to be assisted to the night vessel every fifteen or twenty minutes, for the next hour, and less frequently for he next twenty-four hours. The quantity of urine passed, I believe, was greater than normal. During the last of the next fifteen minutes the interval between the convulsions would occasionally be greater, when it would sometimes be terminated by a more violent surge forward than the one preceding it. I now administered a third dose (twenty-five grains) of chloral.

Twenty minutes after the third dose, and forty-five minutes after the first was taken, general muscular tremors had taken the place of the emprosthotonos to a great extent, the latter not so violent when they did recur, when I administered a fourth dose (twenty-five grains) of chloral. In a few minutes, three or four, after the fourth dose was taken the patient became quiet, and apparently asleep, though occasionally there would be a general muscular tremor, when she would open her eyes for an instant. I then left the patient and returned at 4 A.M., on the 23d, when I found that she had rested as when I left her for about an hour, then was aroused by an emprosthotonotic spasm, though not so violent as heretofore; and since, for more than two hours, she had had four or five such, and perhaps as many general tremors. About three hours after the fourth, I now gave her a fifth (twenty-five grains) and last dose o chloral, and left until 9 A.M., when I learned that she had fallen asleep a few minutes after the last dose was administered, and slept for an hour and a-half, and since, there had been no violent tetanic seizures; but frequent general muscular tremors, which recurred for two or three days, gradually growing less in violence and frequency. Owing to the soreness, stiffness and twitching of the muscles, she could neither stand nor walk without assistance for twenty-four hours. I now learned that the patient was color-blind; all objects appeared to her a yellowish-brown color, and it was not until the 25th, that the color-sight returned entirely.

The patient was more communicative now, having given up, for the present, the idea of taking her life. She gave me a vial containing strychnia in crystals, from which some time during the day of the 22d she had taken, as near as she could judge, one-third of the quantity it then held, concealed it about her person until the aforesaid occasion, when she swallowed it. The messenger told me that then she attempted to take a drink of water, but he prevented her from drinking much. I carefully weighed the remaining contents of the vial, and there was seven grains and a small fraction. There were no remedies administered save those mentioned.

Liegois,* from a series of experiments on animals, concludes that chloral is of great service in antagonizing the effects of strychnia.

Bennet,† from his experiments, states that strychnia is of but little service in chloral poisoning, but finds chloral has greater antagonistic powers over strychnia.

Dr. Angus MacDonald has used chloral successfully in a case of strychnia poisoning.

In a case of strychnia poisoning in a girl of sixteen, Rivine,‡ a German practitioner, has found that 40 grains of potassium bromide and 10.20 grains of chloral hydrate were of great use, while 120 grains of potassium bromide or 40 grains of hydrate of chloral are necessary by themselves. He therefore recommends the combination of the two remedies in the treatment of cases of poisoning by strychnia. To test this theory, his pupil, Hessler, has carried out certain experiments on rabbits. For this purpose Hessler has investigated the mode of action of potassium bromide on the sleep produced by chloral hydrate. He finds that the simultaneous administration of the former drug does not appreciably prolong this sleep. That sensation and reflex irritability are never completely abolished. That the danger of a fatal termination would not be diminished in narcosis produced by the administration of four-fifths of the minimum lethal dose of chloral hydrate with the addition of potassium bromide in a small dose (about one-third of the lethal amount). In ten cases of the minimal lethal doses of strychnia, the method advocated by Rivine was not of more use than the simple chloral treatment; by both methods the tetanus which threatened life was allayed, and consequently life was prolonged. The duration and intensity of the attack were lessened to the greatest extent when the chloral mixture was given. When the minimal lethal dose of chloral hydrate was not exceeded, a sudden diminution in the frequency of respiration, and death from chloral poisoning occasionally occurred. The ultimate conclusion to which the experiments have led is that the simple treatment of acute strychnia poisoning by means of chloral hydrate is decidedly superior to the combined method proposed by Rivine.

—Much complaint is made of the bad air in ferry boats and cars, during this cold winter weather. Proper modes of ventilating these conveyances are still desiderata.

A CASE OF HERNIOTOMY.

BY JAMES MACFIE, M.D., C.M.,

Of Fort Covington, New York.

The susceptibility of the peritoneum to take on inflammatory action when injured has rendered all operations involving parts covered by that membrane extremely hazardous. Hence, surgeons have been always timid about operations involving a solution of continuity of that membrane. While it is undeniably true that operations upon the abdomen frequently result in peritonitis, it is no less the fact that operations such as ovariotomy, in which extensive adhesions have been broken down and large portions of the serous membrane of the abdomen wounded, have resulted, not only favorably, but without any marked symptom of peritonitis.

Some writers have maintained that the frequent tappings to which the cyst has been subjected and the pressure caused by the size and weight of the tumor, have rendered the peritoneum less liable to inflammation, and have, in short, established a sort of toleration of rough handling on the part of that delicate structure, and have thereby rendered safe injuries which in the healthy subject would have ended almost inevitably in a very serious if not fatal inflammation.

May it not be also that the same kind of toleration is established in the coverings of old herniæ, which have been frequently returned by taxis, either at the hands of a physician, or of the patient himself? I have been unable to find where any author has instituted any comparison between cases of herniotomy, such as have been published, with statistics on the difference in the fatal results between cases of amputation from disease and from injury; such statistics, could they be gotten, would be not only of great interest, but also of great value.

The case to which I desire to call the attention of your readers has been of very great interest to me, on account of the very rough treatment which the protrusion received from the patient himself, the peculiar circumstances of the patient, and the very favorable progress and termination of the case.

Alexander F. McR., a stout built Scotchman, of middle age, was married on the 4th of October, 1880. On the 10th, six days later, a hernia which had troubled him at times for many years came down, and McR. found himself unable to reduce it. However, as he had always succeeded in reducing after a time, he was not very much alarmed, but continued to use the means

he had formerly found successful, till Tuesday evening, when I saw him, about 10 o'clock.

Found a right scrotal hernia, very large, and from the amount of manipulation to which it had been subjected very tender, and showing an ecchymosed appearance throughout. In addition to the local lesion, were the ordinary symptoms of strangulated hernia, to wit, an anxious, pinched and haggard appearance, with gulping, spasmodic vomiting. So great was the tenderness that before attempting taxis I applied hot opiated fomentations over the swelling for about an hour, and on attempting to reduce by taxis was enabled to reduce the size of the tumor quite materially. The vomiting also ceased and he expressed himself confident of completing the reduction in due time by continuing the application of the fomentations. Having another patient, whom I could not leave for any length of time, I left, with the understanding that I was to be recalled on the recurrence of the symptoms before mentioned, or on his failure to complete the reduction of the bowel. A messenger came for me about 1 P.M., who stated that his symptoms were no better, if not worse, than in the night. Taking with me my friend, Dr. Berry, of Westville, I visited him and found his condition to be about the same as on the previous night. Putting him thoroughly under the influence of chloroform we again tried taxis, but without success.

We were, of course, extremely desirous of reducing without operation. In view of his recent marriage, our inborn philanthropy and feelings of humanity would make us use every reasonable endeavor to spare the young bride the pain of seeing her liege lord thus prostrated, suffering and helpless. Having failed to reduce by taxis, I proceeded to operate in the usual manner.

On reaching the sac I found it bound down by deep adhesions, and on closer examination found that the patient, in his efforts to reduce, had actually ruptured the sac, and that this was the principal cause of the swelling in the lower part of the scrotum, it being infiltrated by the serous fluid from the abdominal cavity, which had thus found its way into the scrotum.

The sac was opened throughout and the bowel found to be of a dark purple color, but shining and resilient. It was returned to the abdominal cavity. The sac, which was quite firmly adherent, together with a small amount of omentum, was left in the wound, which was closed by sutures and dressed with a carbolic solution. He was given, every four hours, $\frac{1}{4}$ gr. of morph. sulph.

October 14. Appearance good. Haggard look gone. Slept well and flatus passed off freely. A very little tenderness over the right iliac region. Temperature $99\frac{4}{10}$, pulse, 96. Wound looks well, but swelling in scrotum still great, and increasing.

Oct. 15th. Symptoms unchanged; indeed, from this time there was no rise of either pulse or temperature. The scrotal swelling increasing. Wound does not look so well.

Nothing would be gained by giving a presentation of the case from day to day. As already stated, the pulse and temperature remained constantly below 100. The local symptoms, however, were not so agreeable, either to the patient or myself. The serum infiltrated into the scrotum produced an abscess, which occasioned the patient a good deal of anxiety, and discharged very freely. The portion of sac left in the wound sloughed out, after which the wound went on steadily healing, and the scrotum also regained its normal dimensions, till, to-day, Nov. 27th, when I saw him, the wound was nicely healed, and he was able to walk about quite extensively. In fact, I met him walking about three miles from home.

With regard to the operation there is nothing special to note, but the case seems to me an interesting one in view of the force used, which was sufficient to rupture the sac, and after the operation the sloughing out of the sac; and notwithstanding such severe usage to the peritoneum before, and so grave lesions after, there was no notable rise of either pulse or temperature. As to the marriage: was this severe hernial attack *propter hoc*, or was it only *post hoc*?

DIFFUSED TRAUMATIC ANEURISM OF THE FEMUR, WITH OPERATION.

BY W. H. HAWKINS, M.D.,
Of Rocky Comfort, Ark.

On the night of July 19th, 1877, was called to see R. L. N., colored, aged 14. Reached him at 11 P.M., and found him suffering from the effects of a gunshot wound of both legs and one thigh. The boy had been out with other boys on a hunt, and the dogs having "treed a coon," this youngster climbed up the tree to shake the coon out, when his companion below became anxious, and fired the gun at the coon, the shot taking effect in the person of the boy as above stated, to wit:—

Four shot, variety known as "duck shot," entered the outer aspect of the left leg, and passed, superficially and obliquely, upward and inward, being found beneath the cuticle at the inner and lower third of the thigh, were taken

out. My attention was now directed to the right leg and thigh, and six of these shot were found to have penetrated the posterior and inner portion of the right leg and thigh, to wit: Two a little to the left of the outer border of the head of the gastrocnemius, and passed upward and obliquely outward in front of patella, and were extracted. Two entered the inner margin of the popliteal space, and two along the border of the Sartorius. These four passed obliquely upward, through the fleshy portion of the thigh, and were not extracted. It was noticed next morning that the right thigh was swollen and hot. Morphia, to allay pain, absolute rest, with legs and thigh elevated, with cold applications and liquid food, were ordered.

July 20th, 9 A.M. Found boy doing well. No increase in size of right thigh.

23d, 9 A. M. Doing well, thigh diminished in size; slept well.

27th, 9 A. M. Still improving, thigh less.

August 1st, 9 A. M. Improving, thigh less.

August 26th. Parents brought boy to my residence in a road wagon; said he had been walking about; that shortly after he had commenced to walk his thigh began to pain him and had swollen larger than at first.

Upon a minute examination found the thigh a little red and inflamed; ordered acetate lead and laudanum solution, and that he be carried home and not allowed to walk about.

On the 9th of September, 3 P.M., saw my patient and found he had not been doing well; complaining of great pain in the thigh, which had steadily and gradually enlarged. The enlargement was not uniform, but the greatest prominence occupied the muscles on the posterior portion, about the middle.

The parents had supposed the swelling to be what they termed a "rising," and had poulticed. Ordered a re-application of lead and laudanum, and instructed them when they thought the "rising" should be opened to send for me, and this they did on the morning of the 14th.

Dr. Alexander saw the case with me. After examining it we concluded to explore, before laying open the swelling. No pus was found. We then carefully divided the cuticle and exposed a blood clot. As we were not prepared for the emergency, a tourniquet was placed in position over the femoral artery, and the parents instructed how to act in the event bleeding should take place from the cut surface. The evening having been far spent, we left, but early next morning a messenger came for us. We found dark, grumous blood oozing from the opening. The swelling had pointed, and presented a soft, fluctuating tumor, the size of an ordinary hickory nut, between the sheaths of quadriceps femoris and vastus externus, but no rhythm could be heard in it. A lancet was boldly pushed into this prominence, when arterial blood escaped, with regular rhythm.

We now knew we had an extensive diffused traumatic aneurism to deal with, and the time had come to act. The tourniquet was turned upon the femoral artery, a probe inserted into the posterior opening, and moved in every direction. It was put into the more recent opening with like result. The muscles had been greatly destroyed. The parents were notified of what would have to be done, and that in all probability the patient might die on the table. They readily consented to the operation.

He was chloroformed. Dr. Alexander took charge of the femoral artery. We had but little sound tissue at our command for flaps; operated by the circular method, through the upper third, as high up as the stump could be made without interfering with the perineum. The arteries were admirably controlled, and no blood of consequence was lost. With great care in fashioning the stump, enough skin was obtained to cover the end of the bone. After securing the arteries, the stump was left open to glaze. Closed the wound with carbolized interrupted sutures, and anointed it with carbolized oil. The sutures were supported by the usual adhesive strips. Over the whole was placed cloths saturated with carbolized water, to be constantly renewed.

The wound healed by first intention, excepting over the bone, where there was too great pressure, owing to the peculiarity of the operation, viz: the muscles having been cut through at too much of a right angle.

On October 1st the patient was discharged with a good, sound, and nicely rounded stump.

Remarks.—There was nothing unusual about the operation *per se*, but I report it in full that I may call attention to the great care we should exercise in the management of such cases.

From July 19th to Aug. 26th nothing was suspected of a serious nature, but on that day I began to suspect the possibility of having an aneurism, "traumatic." I suspected it from the fact that as long as the boy was kept confined there had been no increase in the swelling of the thigh, but as soon as he was permitted to get up, the limb began to swell rapidly, and to show marked symptoms of inflammation. The parents said they thought it was owing to a fall he had received, and that it was a "rising," from the

shots left in the leg; but I suspected otherwise, and hence the call for counsel and the careful exploration on the 14th of September, nineteen days after I first suspected aneurism.

By permission of parents, we carried the limb home, and Dr. Alexander made a careful dissection of it.

I herewith append the doctor's report:—

"In dissecting the amputated limb, I proceeded as usual, removing the integument, fascia, etc., and laying back the muscles. Upon removing the Sartorius muscle and the dense fibrous band extending from the vastus internus to the adductor muscles, a large clot, as much or more than would fill both hands, was discovered. After carefully removing it, a long straw was introduced into the open end of the femoral and profunda arteries, and the straw came out of each, nearly opposite where the profunda passes under the superficial femoral; so that one shot might have wounded both arteries. The opening was very small in each. I suppose the clot acted as a ligature, so as to prevent a rapid flow of blood, but allowed a constant oozing. The treatment also had a tendency to prevent a rapid flow. The wounds in the arteries were in the middle third, and the clot filled the entire third of the thigh."

Hospital Reports.

PENNSYLVANIA HOSPITAL.

SERVICE OF DR. JAMES H. HUTCHINSON.

REPORTED BY GEORGE F. SOUWERS, M.D.

Gentlemen:—I propose, this morning, to consider with you some cases of liver disease. It is not an uncommon occurrence in the practice of medicine for the practitioner to come in contact with certain diseases which, while they bear so close a relationship to each other, in both their symptomatology and prognosis, as to have been classed under one and the same grand head or name, yet present pathologically or in some manner a number of points of difference. In illustration of this proposition, I shall begin my lecture by exhibiting to you the liver and certain other of the organs removed from the body of a patient who has recently died in my ward. The following is the history of the case:—

E. B., aged 48, a widow, and by occupation a charwoman, was admitted to the hospital November 2, 1880. Her family history was good, and she herself enjoyed general good health till the onset of the disease which carried her off; menstruation was performed regularly till two years ago, when the menopause occurred; she had eight children, two of whom are now living. In searching for the original cause of her illness, we elicited the fact that seven years ago she fell from a step-ladder, striking heavily on her right side. From the time of the receipt of this injury to the time of her death the bladder seemed to be weak and irritable, the urine at times dribbling away, thus being a source of great annoyance to the patient. During the past summer she was weak and miserable, the appetite very poor, and a constant loss of flesh taking place; there was also present a great deal of pain in the small of the back. Nine days before her admission, after having been exposed to cold and wet, she was suddenly taken with purging and tenesmus, the bowels being, as she expressed it, drawn into knots, and the abdomen being very tender on pressure; the passages were sometimes milky and sometimes yellowish, and streaked occasionally with blood, and very frequent. (I may say here, however, that she has never passed any blood since coming into the hospital.)

The notes of her case, from the time of her admission to the wards up to the time of her death, read as follows: "Patient emaciated and weak, the skin and conjunctivæ yellowish in color. Tongue dry, coated with a white fur, and indented by the teeth; the skin very dry. She has a slight cough, there is dullness over the base of the left lung, a few râles are heard, with blowing respiration, crepitation, and bronchophony. The abdomen is very painful; the patient is unable to keep anything on her stomach; the bowels are loose, the passages being thin, yellowish, and frothy. Urine dribbles away, and is dark, cloudy, and alkaline in reaction, and contains an abundance of urates, but no albumen. Percussion during life showed that the liver extended three fingers' breadth below the arch of the ribs, and the liver dullness extended higher than normal; over its front surface no distinct nodules could be felt, but low down in the right lumbar region there was felt what appeared to be a nodular mass about the size of the fist. There was tenderness on pressure over the whole of the liver, but the patient made no complaint of lancinating pains, either in the hepatic region or elsewhere.

Before proceeding to discuss the pathological appearances, etc., I will speak of the diagnosis, prognosis, and treatment of the case. Taking into account the fact of tenderness over the liver, associated with the excessive diarrhœa, one would naturally assume that abscess of the liver was the disease with which we had to deal; the stools, however, I may here say, did not present a dysenteric appearance; further, there was not at any time any fluctuation present, nor was there any attempt at pointing, as we should expect if an abscess were present. Finding the liver enlarged and the nodular mass present in the right flank of the organ, I was tempted at first to conclude that I had to deal with cancer of the liver; but this conclusion I did not feel warranted to adopt positively, on account of the following considerations, namely: That though there was jaundice present, yet it was not of that intense character which, if the symptom is present at all, is apt to be associated with the other symptoms of this disease; although the disease had lasted for some months, the organ was not enlarged to that extent which it would have presented had cancer been at the root of the trouble; neither was the sharp pain of malignant disease present, so that, as I say, I was not able

to convince myself that cancer was the disease to be contended with. There is a rare disease known as hypertrophic cirrhosis, with icterus, and I think that my patient fell a victim to this trouble; it is a form of cirrhosis not often seen, in which the contractile or retrograde changes of ordinary cirrhosis are not present; the hypertrophic changes seem alone to predominate; like ordinary cirrhosis its treatment is unsatisfactory and its prognosis unfavorable.

On referring back to the notes of the case I find that on her admission she was ordered pulverized ipecac, grain xx twice a day, and opium suppositories, to check the diarrhœa; liq. calcis, whisky and milk were employed, to allay the vomiting and to stimulate and nourish the patient. Being placed on this regimen we find the notes continued as follows: November 6. Diarrhœa somewhat checked, less vomiting; patient has been taking laudanum, gtt. xv, enemata, $\frac{1}{8}$ of a grain of opium and 1 grain of tannic acid, every 3 hours.

November 13. Tongue much the same; more jaundice present; the liver extends to within one inch of the umbilicus. Has not had any diarrhœa or sick stomach for several days; lungs resonant; tenderness still present over liver.

November 16. Patient weaker and delirious; more emaciated; slight vomiting again present. She yesterday had a formed passage; several bed sores have formed, and abdomen is very tender.

November 17. Subsultus present; fast becoming weaker: ordered turpentine, gtt. x, three times a day.

November 21. Unable to swallow.

November 22. Died, about 5 A.M.

I here show you the post-mortem appearances of the case, and shall read you extracts from the notes of the pathologist of the hospital.

The examination was made nine and a half hours after death, rigor mortis being present. The left lung, over which you remember there was dullness, is bound down by old pleuritic adhesions, there being no effusion present; on the right side the same appearance is presented. Both lungs are emphysematous and full of small nodules, these being both soft and hard, those in the left lung being somewhat more coalesced; there is some gray hepatization present, and the condition known as chronic catarrhal pneumonia is well shown. The glands at the root of the lung are enlarged and calcareous. The heart, arrested in systole, presents a chicken-fat clot in its right cavities, black clot and some fluid blood being found in the left auricle; the valves are normal; in the great vessels going off from the heart ante-mortem clots were found. The weight of the organ is eight ounces. The left kidney is irregular in shape and granular in appearance; its capsule is more adherent than normal, and it weighs about $4\frac{1}{2}$ ounces. The right kidney presents much the same appearance as the left, but weighs only three ounces. In some of these cases I have seen the kidney weigh but seven drachms. The spleen is enlarged, and shows evidence of a chronic capsulitis, it weighs $6\frac{1}{2}$ ozs. The pyloric end of the stomach is contracted. The colon presents in its course a number of ulcers, its mucous membrane being softened and detached in places; at the same time the tube does not present the pathological appearances of dysentery. The most interesting organ yet remains for discussion, I refer to the liver, whose weight is four pounds four ounces, and whose fibrous tissue is greatly increased; the organ is enlarged, thickened, mottled, nodulated, and presents a nutmeg appearance; on pressing my thumb into its substance I find it to be hard and resisting; its capsule is adherent; the duct is perfectly patulous, but during life was obstructed by the enlarged glands in the fissure of the liver pressing upon it. The mesenteric glands are, as you see, greatly enlarged. The small intestines are inflamed, the mucous membrane being swollen and peeling off in places.

I have attempted to give you a description of this disease, in which, contrary to what occurs in the ordinary forms of cirrhosis, contraction never or rarely takes place. The hypertrophy continues, usually, as long as the patient lives; although I may mention here that hypertrophy of the liver is frequently observed in the first stage of the more ordinary form of cirrhosis, which we shall now discuss, as presented in the case of E. W., now before you. I shall give you, first, the history of the case as taken from the hospital case book. She is a widow, and a housekeeper, aged forty-two, and was admitted into the wards November 15th, 1880. Her father and brother died of phthisis, her mother of dropsy: she herself has been generally strong and healthy. Nine years ago she had inflammatory rheumatism, for which she was treated in this hospital; neither dyspnœa nor heart trouble of any kind followed this attack, and she has had no sickness since. She has never had any children, and menstruated regularly till nine months ago, when the menopause occurred; she presents no specific history. She claims to be temperate, but this we know to be questionable, as she has twice presented herself at the gate of the institution under the influence of liquor. About three weeks ago she got wet and cold; about a week after she noticed that her abdomen was swollen and painful, and that she had lost her appetite. A week previous to her admission to the hospital her feet commenced to swell, her abdomen being very much swollen and very painful at this time; her stomach rejected nearly everything swallowed; there was no headache nor pain in the back present; at and after the onset of the swelling of the feet she ceased to pass urine in any quantity; further, at the time spoken of jaundice was present.

Upon admission, the patient is spoken of as being anæmic, and slightly jaundiced; the abdomen is distended, tense, and very sensitive, the veins of the abdomen are decidedly enlarged, the lines of dullness over the abdomen shift with the position assumed, thus showing the presence of ascites; the liver, on percussion, appears rather contracted. Over the middle of the right lung posteriorly some friction sounds are heard; percussion elicits more or less dullness; in the left lung a few râles are present. A murmur is heard over the apex of the heart, and with the first sound there is some friction associated. Urine acid, dark, and contains urates and bile, though no albumen. She was ordered at once mist. Basham, half an ounce every three hours, and

the infusion of digitalis, one drachm at the same intervals; the bowels being constipated she was directed to have an enemata.

November 17. Sounds over the heart more marked, and bear still more of a resemblance to friction sounds. As she was weak, she was ordered, to-day, four ounces of gin.

November 18. To-day no friction or murmur of any kind could be heard over the heart, but there was some increase in the pericadial dulness. The abdomen painful. The gin does not seem to agree with her, as it makes her sick at the stomach. Posteriorly, over the base of the right lung, there is dullness; respiration is bronchial and distant, fremitus diminished. Instead of gin, whisky was administered, and an ointment of equal parts of belladonna and iodine was applied over the abdomen.

November 19. Passes more water and abdomen less tense.

November 20. Dullness over spleen appears increased; fremitus is increased and bronchial breathing is more marked over the lower part of the right lung. She complains of bleeding piles, which give her a great deal of uneasiness, and for these five grains of tannic acid and ½ gr. of opium in suppositories is ordered.

November 22. Abdomen less tense, though still tender. She looks decidedly better. There has been no return of the friction murmur, and there is less sick stomach. As I look at her to-day I find that she is less jaundiced than she has been heretofore. This symptom is more marked and noticeable in the eyes than in the skin; you will notice that the conjunctivæ present a decidedly yellowish discoloration. At times we have a dirty discoloration of the skin, somewhat resembling jaundice, present in chlorosis and anæmia, but in these latter disorders the conjunctivæ usually present a peculiar pearly whiteness; the jaundiced condition of the skin can best be observed by making decided pressure upon the forehead, the blood being thus squeezed out, the integument presents a peculiar parchment-like yellowness; now you must not in any case regard jaundice as a disease, it is simply the expression or symptom of some morbid action taking place in the economy.

Upon looking at the abdomen we find it enlarged, and its integument deeply pigmented; on the right side, over the locality of the liver, the superficial veins are very prominent, and there probably exists in these vessels a reversed current; the portal circulation being interfered with, the superficial vessels must assume an unusually large share in the function of circulating the blood. At first, palpation of the abdomen gave exquisite pain, but I can now exert a good deal of force without eliciting any unusual sensation; upon palpation in the neighborhood of the liver I can discover no enlargement whatever; in fact, on the contrary, I find that the lower edge of the organ occupies a much higher position than it normally should. Fluctuation, while present, is not so marked as is generally the case in disease of the character under consideration; upon tapping on the abdomen there is a distinct wave propagated from one hand to the other, which wave is not propagated by the abdominal walls, as can be proved by letting an assistant place his hand upon the abdomen, in the line of the umbilicus, and then palpating. This, of course, prevents the transmission of a wave by the abdominal walls, but does not prevent its transmission through liquid contained in the abdominal cavity.

Again, by placing the patient in different positions, I find that the lines of dullness vary or shift, the dullness being always present in the most dependent position; thus, if the patient be placed on her hands and knees, the dullness is found in the neighborhood of the umbilicus; if placed upon her back or on her feet, the line again shifts, due, partially, to the different positions assumed by the bowels, their presence always being made manifest by more or less resonance; now, in ovarian dropsies the dullness is more stable, being bound down, as it were, it is not able to shift around from one locality to another, and, as a general rule, occupies the front of the abdominal cavity.

By these different examinations, I demonstrate that there is a peritoneal effusion present. Now, we may have other diseases than cirrhosis producing an ascites; thus cancer of the liver and peri-hepatitis may give rise to the symptom. But in all cases of dropsy dependent on liver disease the cause of the ascites is the same, namely, the compression of the portal vein and its branches, the connective tissue development in circhosis taking the place of the true liver tissue. When the organ begins to contract, an undue amount of pressure is exerted upon the veins; the blood being dammed back must thus relieve itself by an effusion into the abdominal cavity; or else there takes place a hemorrhage from the bowels, the delicate vessels of the intestines, unable to stand the pressure exerted, rupturing and allowing the extravasation of their thin contents.

In this case relief has been afforded to the engorged circulation by the formation of bleeding piles, and it is due to this fact that we have so little ascites present. A cancerous nodule pressing on the portal vein will produce a very marked ascites; in peri-hepatitis, also, we may and do have an effusion taking place, though this is within the capsule of the liver. If, however, the ascites present in this case were due to the presence of malignant disease, the hepatic dullness, instead of being decreased as it is, would extend over an enlarged area: we have here but little or no peri-hepatitis. Owing to the effusion, the liver is floated up very high, and probably less of its surface presents to the percussing finger than normally. The abdomen, on pressure, is tender; so I think that, perhaps, we may have here to deal with a certain amount of peritonitis (as well as cirrhosis) localized in different portions of the abdomen, but especially marked in the region of the liver; this is not an uncommon accompaniment of liver cirrhosis. I am inclined to this peritonitis theory from the fact that in this case two other serous membranes have been inflamed, as evidenced by the pleural and pericardial friction sounds; the dullness posteriorly, the enlargement discoverable on percussion in the præcordial region, and the presence of a few râles, all go to sustain me in this view. As to the cause of all this trouble in the liver there can be no question; she denies being a drink-

ing woman, but I have had every evidence to the contrary; further, alcoholism we know to be the exciting cause and foundation of nearly all cirrhoses of the abdominal viscera; true, it may, perhaps, occur idiopathically, but it is then an exception to a well-proved rule. The prognosis of these cases is unfavorable, both as to life and recovery. I do not think that after structural changes of any kind have taken place in the liver there can be any remedy; the only thing to be done is to relieve the most urgent symptoms, and make the patient comfortable. The pathology consists, first, in an inflammatory condition taking place in the liver structure; this is followed by the appearance of connective tissue bands, substituting the true liver tissue; these bands, after some little time, beginning to contract, result in a shrinking of the normal size of the organ, which, in the first or inflammatory stage, seems to be hypertrophied.

As to the relief of symptoms, and the general treatment of these cases. If the breathing was greatly interfered with it might be advisable to tap the patient, and thus remove the water; but this proceeding is not entirely free from danger, as, instead of a localized, we might have a dangerous general peritonitis set up. If, however, the symptoms were urgent, which in this case they are not, the operation would be justifiable. If necessary, the bowels and kidneys may be called upon to perform extra duty, for the purpose of removing the effusion; one drachm of the infusing of digitalis, and a tablespoonful of Basham's mixture, every three hours, have produced very good effects in this case; the objection to the use of purgatives is that they produce too much of a drain on the system; elaterium, while it would rapidly remove the ascites, would at the same time further weaken our already debilitated patient. The diet should be light, easily digested, and nourishing; the patient being permitted, when possible, a judicious amount of out-door exercise.

Medical Societies.

ACADEMY OF MEDICINE AND SURGERY OF KENTUCKY.

PROCEEDINGS OF THE MEETING HELD DECEMBER 2, 1881.

REPORTED BY A. H. KELCH, M.D.

Ophthalmic Pathology.

Under the call for "presentation of pathological specimens," Dr. D. S. Reynolds exhibited several eyes, and in presenting them made the following remarks:—

There is an interesting history connected with these specimens. This is the skeleton remains of an eye the vision of which had been lost many years ago, from a neglected inflammation of the iris. It is plainly perceptible, from the mass before you, that the globe must have been not less than two inches in diameter. About five years ago the last perception of light disappeared. The unfortunate subject from whom this specimen was taken was about 38 years of age, and had been living in a malarious district in the southern portion of this State. He suffered from an inflammation of the iris, which, as I remarked before, was neglected, until finally it involved the ciliary body and extended its ravages to the choroid. Dropsical effusion then took place, distending the globe so much as to make serious pressure upon the structures between it and the orbit and to produce such irritant effects upon the brain as to cause epilepsy, for which he had been ineffectually treated by prominent physicians and quacks in the cities of St. Louis, Cincinnati, Philadelphia and New York, within the last five years. He had been given nitrate of silver, bromide of potassium, atropia, nitrite of amyl, and all kinds of treatment known to the profession.

In the last two or three months previous to his visit to this city he had suffered as many as three attacks per month; and, probably on account of the excitement induced by the thought of an operation, after his arrival here had two attacks in twenty hours.

I enucleated the eye which I here present, and he has not had a particle of headache since. It is now three weeks since the operation was performed, and up to this time he has had no return of the epileptic seizures.

He is a man well nourished and of great muscular power, and had never been sick until about eight years ago, when he had what he considers an attack of neuralgia in the right eye. This was followed by the slowly collecting effusion, the pain becoming more of an aching character, often extending from the temple to the occiput. Five years ago he had an attack in the left eye, of a similar character, and shortly after that he lost the sight in this eye. I report this case to show that although the amount of pain and distention was something unusual, the nervous system was so influenced as to cause epilepsy. It is not common to see the ball so distended as to be almost immovable. In this case it was necessary for me to cut into the distended walls of the globe before the muscular and connective tissue attachments surrounding the ball could be severed. There was not sufficient room to seize the muscles between the distended globe and the orbit. The remaining eye is quite free from irritation, and in consequence of that fact, it was allowed to remain.

Specimen 2.—Here is an eye that was taken from a young lady two months ago. The eye had been injured in infancy, by a puncture with a pair of scissors. The remarkable feature of this case is that, although the puncture was made through the slero-corneal junction and ciliary body, and the eye shrunken to a mere stump, the young lady had gone to school and obtained an education, and had never suffered any inconvenience nor discomfort in the use of the fellow eye.

Here was a puncture inflicted when she was but three years of age, and she is now nineteen, the shrunken globe remaining all this time without causing serious pain or other morbid manifestation in the opposite eye. It is almost universally believed by specialists that an eye destroyed by a punctured wound of the ciliary body is certain, if allowed to remain, to set up what is known as sympathetic irritation in the fellow

eye, which will lead to fatal results, so far as the vision is concerned. Mr. George Lawson, in the reports of the Royal London Ophthalmic Hospital for 1872 or '73, records the case of a man who had lost an eye from injury; the globe underwent atrophic changes, such as are shown in this specimen, and the man had gone on about forty-two years without suffering any inconvenience in the other eye, when suddenly a sympathetic irritation became manifest in the opposite eye, which soon began to grow dim, and in a few weeks he was admitted to the hospital, with bare perception of light. Though the lost eye was, on his admission to the hospital, removed, the opposite one went on to complete blindness, and Mr. Lawson was sure the one eye could have been saved by the timely removal of the blind eye.

Specimen 3.—This is the eye of a gentleman only twenty-eight years of age; it was destroyed by the kick of a mule, eight months before he came to have it removed. The calk of the shoe worn by the mule struck the man on the temporal margin of the cornea, and ruptured it. An intelligent gentleman, who was somewhat acquainted with the structure of the eye, told him there was a rent just within the cornea, on the temporal side. In this specimen, as you see, the whole cornea has been removed by absorption, and the atrophic changes which followed by continuity of structure, producing contraction of the whole globe. In September the eye became tender and painful, but it seemed to get well again, and about the middle of October it was again affected, and this time the sound eye grew sensitive and watery, which led him to consult a physician, who told him to consult a specialist. This attack subsiding, he waited another week, when he was again attacked, and with corresponding dimness and morbid sensibility to light in the fellow eye.

When he came I removed the eye, although there was considerable irritation at the time. The other eye remained a little sensitive to light, and was somewhat dim for two weeks. After that time a test of the vision revealed about the normal acuity. About six weeks after the removal of the eye he came back to get an artificial eye; and, though the structures seemed to have regained their normal condition, all signs of irritation having disappeared, the instant an artificial eye was introduced he suffered pain, and lachrymation of the other eye. I advised him to return home for the present and return in two months.

Specimen 4.—This eye has a much sadder history connected with it. The young gentleman to whom it belonged had the misfortune to contract a gonorrhœa on the 4th of July. About the middle of the month he discovered he had something the matter, but it did not occur to him at the time that it was due to the exposure on the 4th, and he paid little attention to it. He was spending his summer vacation in a general frolic, and came here to Louisville to look around. While here he came to my office to deliver a message from a physician in the neighborhood where he lives. He told me he believed he had gonorrhœa. I sent him to a medical friend and soon had forgotten all about him. About ten days afterward his physician called and told me he believed the young gentleman had lost one of his eyes, and he desired me to go and see him. I found the right cornea had sloughed out *en masse*, and the left was becoming hazy. Careful attention succeeded in saving the left eye, but the right affords the specimen before you. This shows the importance of early attention to gonorrheal ophthalmia. There is an important lesson to be derived from a study of these cases. They show, in the first place, that though an eye be absolutely blind, it may give rise to so much irritation as to cause epilepsy in a strong and vigorous man. Another specimen of an eye destroyed in a manner most likely to create serious trouble, is followed by no inconvenience or discomfort in the use of the opposite eye. Here is another case with only the cornea lacerated, no other part damaged, that gets well and in a few weeks after recovery he begins to suffer recurrent attacks of inflammation in it, which causes sensibility to light in the opposite eye, and the patient is threatened with a sympathetic ophthalmia.

Another, a young man in good health, contracts a gonorrhœal inflammation, and, failing to give prompt attention to it, remains in the obscurity of a boarding-house until the eye sloughs nearly out, and the remainder must be removed.

To-morrow will be three weeks since three gentlemen, on the Ash Creek Road, were out shooting birds. While they were considerably separated, a covey rose, and the gentleman at the extreme left fired toward the right, and a shot struck one of his companions in the right eye, passing through the cartilaginous portion of the upper lid and through the sclero-corneal junction, directly in the vertical meridian. He came to see me in less than an hour after the receipt of the injury. The anterior chamber was filled with blood, and there was a large rupture at the point indicated, showing that the shot had penetrated the globe. I gave him a purgative dose of calomel, and ordered a solution of atropia and morphia, and directed him to bathe the eye with cold water, and under no circumstances to cover it up. In a few days the wound healed and the blood disappeared. At present a normal condition of the aqueous chambers is present, except where the shot came through the wall above. Careful examination shows no detachment of the retina; the red reflex from the fundus may be seen all round, and the shot must be very near the ciliary body in the anterior and inferior portion of the globe. He has had but little pain in it up to this time, and, strangely enough, there has been no inflammation of the damaged iris except at the point where the shot entered. He was able to count my fingers yesterday with that eye; and while I have no hope of saving the vision, I have some hope of the shot being encysted and keeping quiet. If it does not, however, I propose, with his consent, to perform optico-ciliary neurotomy. It will probably save him what appears to be a good eye, which is much more convenient and better looking than any artificial eye can possibly be made.

Croup, with Tracheotomy.

Dr. F. C. Wilson. I may mention two interesting cases I have met with in the last five days. Last Sunday, I was called to see

a little girl, eight years of age, who had been sick for two or three days, with what was thought to be croup. All the domestic remedies for such troubles had been tried, and when I saw her first she was breathing with great difficulty, both inspiration and expiration being labored. She had a muffled, croupy cough, and a temperature of 101½°, quick pulse and a tendency to cyanosis. I informed the parents at once that the child was very ill, as I felt satisfied it was a case of membranous croup. I ordered an emetic of turpeth mineral, and for the night five grains of Dover's powders, also, as a local application, cold compresses, to be frequently changed. I saw her again next morning at eleven. She had freely vomited, and had thrown up one or two little shreds of organized material, along with a considerable quantity of very tough mucus, and she was somewhat relieved. That night she rested easier until about six A.M., when there was much more obstruction, and a good deal of cyanosis. I administered oxygen, which restored the red color to her lips, and I then suggested to the family the necessity for tracheotomy, which met with great opposition, as I knew it would, the family being German. The next forenoon I called Dr. Octerlony in consultation, and we agreed at once as to the diagnosis, and the only change in the treatment suggested was the addition of five-grain doses of carbonate of potash every half hour. In the afternoon the obstruction had increased, the respiratory murmur was feeble on both sides of the chest, and a whistling murmur was present, from the obstruction. I again suggested tracheotomy. They still refused.

At 9 P.M. she was worse, and at 9.30 her father came and said if I thought the operation could offer any hope, they would consent. I thought the hope then a forlorn one, but I went at once, and, with the assistance of a druggist in the neighborhood and what few instruments I had at hand, and what I could improvise, I determined to open the trachea and insert a tube. I made an incision through the skin, and was delayed a good deal by the capillary hemorrhage. Finally, the trachea was opened, the lips of the wound separated, and the child breathed with comparative ease. I had suspicions, however, that the membrane extended below the point of incision, and these suspicions were confirmed by the introduction of the tube, which had to be immediately removed. I concluded to hold the edges apart, in order to let her breathe more easily, and I could distinctly see the yellowish-white membrane obstructing the trachea below the point of incision; but at no time did she breathe with that quiet ease which is noticeable in cases where the membrane does not extend below the point of incision. In this case it was merely temporary relief. I held the edges apart for three or four hours, when the necessity caused me to improvise a speculum, which I made out of a hair-pin. This I found to answer every purpose, but the child died at half-past four the next morning.

That afternoon I was called to see a little German boy, five years old, sick two days in the same way. I found his fingers and lips blue, obstruction in both inspiration and expiration, and the same kind of muffled cough noticed in the other case. I explained to the father the great danger the child was in. After prescribing an emetic of Turpeth mineral, I promised to see it again in the evening. Accordingly, at 8.30 I went out and found the child dying.

These were two fatal cases in the same day. I have met with twelve in all my experience, and of the twelve cases have succeeded in saving four. Two I saved, I believe, by the inhalation of oxygen gas, keeping the patient alive until the membrane was detached and expelled; in a third I attribute the relief to the inhalation of lactic acid, and in a fourth to the insufflation of pepsine, and inhalations of lime and bromide of potash and the carbolic acid spray, to which I attribute the most importance.

Editorial Department.

Periscope.

Artificial Respiration in Newborn Infants.

At a recent meeting of the Royal Medical and Chirurgical Society, Mr. F. H. Champneys read a paper to show the amount of respirable air furnished infants by the various methods of artificial respiration. The number of bodies experimented on was twenty-six; only such as had never breathed being used. Tracheotomy having been performed, a cannula was tied into the trachea, the cannula being connected by an India rubber tube with a V-tube filled with water, which thus registered inspiration and expiration by the rise and fall of the water, the results in the same body only being compared, and the highest effect being the standard of comparison. The methods used were nine, viz: those of Marshall Hall, Howard, Silvester, Pacini, Bain, Schücking, Schüller, Schroeder, and Schultze. The conclusions were the following:—

1st. Since the position of equilibrium of a stillborn child's chest is one of absolute respiration, airlessness, or collapse, no method which depends on elastic recoil of the chest walls will introduce air into its lungs. The methods of Marshall Hall and Howard are useless as means of directly ventilating the lungs of stillborn children. 2d. Silvester's method, and its modifications by Pacini and Bain, introduce more air into the lungs than any other method. 3d. In using Silvester's method, the arms should be held above the elbows, and everted. 4th. In using Pacini's or Bain's method, the legs should

be fixed; the second half of Pacini's method, and Bain's second method, should not be employed, as the weight of a new-born child's body is insufficient counterpoise to the necessary traction. 5th. In using these two latter methods, the operator may face the subject, and lift the shoulders from below; by this means he is able to watch the child's countenance, and is able to introduce an equal quantity of air. 6th. Schücking's method is no improvement on Silvester's. 7th. Schüller's method is useless, and not free from risk. 8th. Schroeder's method is useless. 9th. Schultze's plan, although its power of ventilation is less than that of Silvester and its modifications, yet acts efficiently. 10th. In Schultze's method, the diaphragm does descend, though but slightly; its principal action, however, is on the thoracic walls, as in the Silvester group. 11th. In Schultze's method, it is important that the whole weight should rest (at the end of the inspiratory movement) on the index-fingers in the axillæ, and should not be distributed to the other fingers. 12th. The violence of the action of the method of Schultze is not in its favor. 13th. Opisthotonos always produces respiration by tension of the anterior body walls, and should be avoided. Behm's experiments, six in number, dealt with children truly stillborn in two cases only (one other having failed). His general conclusions spoke highly of Marshall Hall's and Howard's methods, which, however, in the two above cases were nearly or quite failures.

The Treatment of Typhoid Fever.

A debate at one of the London medical societies, recently reported, well illustrates the prevailing opinion on this topic across the water. Dr. Bristowe dealt with the subject under the heads of food, medicines, alcohol and baths. A milk diet was urged as of chief importance. Dr. Bristowe doubted if any remedies had direct effect in controlling hemorrhage. Alcohol was not necessary, except in a few cases, when it should be given for its stimulant effect. As to baths, he doubted their efficacy, and thought that if they were as valuable as statistics showed, their good effects should be obvious whenever they were tried. In two cases he had had, he thought fatal pulmonary congestion had been produced by the use of baths. He concluded his remarks by sketching the manner in which he himself would wish to be treated were he the subject of the fever. Dr. Broadbent, who followed, thought the diet should not be wholly restricted to milk, which it was important to give only as food, and not as a drink to relieve thirst, for diarrhœa was often produced by the undigested curds. Sometimes beef-tea set up diarrhœa. Besides correcting the diet when diarrhœa was present, he would use opium enemata. In cases of hemorrhage he gives large doses of opium to arrest peristalsis; ergot and turpentine were also useful. Opium was also of great value in the relief of tympanites. He described his attitude toward baths as one of gradually increasing confidence. Dr. Cayley read a letter from Dr. Brand, of Stettin, giving some remarkable statistics from the military hospitals of Germany in favor of the bath treatment—a chief element in success being the adoption of the method at the very onset of the disease. This was possible in private practice and in military hospitals, but not in the civil hospitals, where patients do not seek admission until they are compelled to do so by the advance of the disease. In Germany it had been found possible to carry out the bath treatment in private practice. The treatment was certainly not a dangerous one. Dr. Norman Kerr made some remarks, in which he admitted the need of the medicinal use of alcohol in some cases of the disease. Dr. Collie said that of 100 cases seventy-five would get well with simply good nursing, fifteen would die, and the remaining ten might or might not recover. Such was his experience, and he had abandoned the bath treatment, as not only useless but even dangerous. He could not put faith in continental statistics, and thought that many cases of mistaken diagnosis were included in them. Dr. Ord had certainly seen good effects from the use, not of cold but of slightly tepid baths in selected cases of high pyrexia, which he believed had a relative effect as well as a control over the whole morbid process of typhoid fever. Dr. Mahomed spoke in favor of the cold-bath treatment. He also mentioned a case of severe hemorrhage which he had recently successfully treated by transfusion.

The Effects of Varicocele on the Testicle.

At a meeting of the Clinical Society, of London, Mr. P. Gould described this subject:—

Two men were shown to the Society, each presenting a large left varicocele, with the testicle on the same side much smaller than its fellow, but retaining its usual firmness, outline and testicular sense. The one man, æt. eighteen, noticed the swelling in the scrotum accidentally, four or five months ago. The other, æt. seventeen, had noticed the varix for six or seven years. In neither case was there any pain or disturbance to be traced to the varicocele. Neither patient had suffered from inflammation of the testicle or any injury to the scrotum. They were both well made, robust, healthy-looking men. Mr. Gould quoted the views of Sir James Paget and Mr. Curling as illustrating the opposing doctrines on the question whether varicocele does or does not cause wasting of the testicle. After enumerating a list of authors who support Curling in his opinion that atrophy of the testicle does result from varicocele, he observed that many of the cases cited in support of this assertion must be excluded, on account of the traumatic origin of the varicocele; wherever there was a history of injury or inflammation it was impossible to say that the change in the testicle was not the direct result of such injury or inflammation. Again, cases where there was no mention made of the presence or absence of these conditions were also of doubtful value. With these reservations the alleged cases of atrophy were of three kinds. First, cases of arrested development of the testicle, illustrated by the cases shown. Second, cases of very slight lessening of the size of the testicle, said by many authors to be very common; a condition

difficult to be certain of. Mr. Gould had never seen the left testicle larger than the right—its normal relation—when there was a large varicocele on the same side. Third, cases of morbid and extreme softening and wasting of the gland. Although cases of this kind are recorded by Curling, Richter, Landouz, and others, no mention has been made of the absence of previous injury or inflammation of the testicle, and they are not entirely free from doubt on that account. There is strong reason to think that varicocele may produce such wasting of the gland. Referring to the frequency of varicocele on the left side, Mr. Gould argued that neither the greater length of the spermatic vein on that side, nor its lying beneath the sigmoid flexure, nor mode of entrance into the left renal vein was sufficient explanation. It was maintained that the use of the valve at the mouth of the spermatic vein was to convert the direct opening into an oblique aperture, and by lessening its size caused the flow of blood over it to exert an aspirating effect. Many differences between varicocele and other external varices were pointed out, and the opinion was advanced that many cases of varicocele are nævoid in character; a primary abnormal development of the veins.

The Uterine Membrane in Menstruation.

In No. 13, *Centralblatt für Gynakologie*, for the year 1880, Dr. Möricke, of Berlin, contributes a short paper on the much vexed question of the condition of the mucous membrane of the uterus during menstruation. The author remarks upon the extreme difficulty which an unprejudiced mind experiences in accepting the view that during menstruation the mucous membrane of the uterus is completely or partially lost, since menstruation, which every one allows to be a physiological process, is made in that way to play the part of a degenerative process, and thus becomes essentially pathological. The author ascribes the results obtained by former observers, who maintain the complete separation of the mucous membrane, to the fact that they had examined preparations which were not quite fresh, and holds that the changes which they saw and declared to be characteristic of menstruation were post-mortem changes. Though this sounds rather strongly, it is, the author maintains, correct, and he thinks that every one who is acquainted with the rapid destruction of mucous membranes after death will readily believe the statement, more especially when he knows how soft and swollen the mucous membrane is during the menstrual process. The method adopted by the author to obtain perfectly fresh preparations, which might withstand the strictest criticism, consisted in introducing a sharp curette into the uterus and removing large portions at will at different times. Thereby a large amount of material was obtained, taken during the different days of menstruation, or before and after its occurrence. In every one of these the epithelial covering was completely retained. In no situation was it even partially destroyed; in many places it was sprung over a small extent, being raised up on underlying blood extravasation, but still it adhered together, and cell for cell of the loosened superincumbent portion was sharply outlined and easily to be recognized. These observations were found true on the fresh and on the prepared specimens. On the former no fatty degeneration could be recognized, even with the greatest willingness to detect it.

On the Occurrence of Albuminuria in Healthy Men.

Professor J. W. Runeberg, of Helsingfors (*Deutsches Archiv für Klinische Medicin*, Band 76, quoted in London *Medical Record*), reviews at length some of the principal contributions, which have appeared during the last few years, to the solution of the problem of the clinical significance of albuminuria. The observations of Leube, Ultzmann, Moxon, Dukes and Saundby have established the frequent occurrence of albuminuria in persons who do not present any other signs of kidney disease. A few years ago such cases of latent albuminuria were regarded as instances of granular kidney, but their frequency makes this improbable. Bull has suggested that the albuminuria indicated a Bright's diathesis or tendency to Bright's disease, and Johnson has stated that such cases, if not cured, pass on to organic kidney disease; but this can hardly be considered as finally settled. The transudation of albumen, according to Runeberg, depends upon an abnormal permeability of the walls of the glomeruli, and this permeability in its turn depends upon the blood pressure. As he has shown, the filtration of albumen through animal membrane is increased by low pressure and diminished by high pressure, so that the old dogma, that the amount of albumen is directly proportional to the pressure on the glomeruli, must be abandoned or reversed. It is well established that active muscular movements increase albuminuria, but this is probably due to the lowering of blood pressure in the glomeruli, a circumstance which is indicated by the diminished secretion of urine, and is supported by the physiological experiments of Ranke, which show that, owing to the large amount of blood flowing into the active muscles, the internal organs have their blood pressure lowered. Moreover, Bartels pointed out that in real cirrhosis the albuminuria is greater in the day than at night, which he attributed to the increased pressure due to the upright position.

Esmarch's Latest Improvements.

Professor Esmarch, in a recent address, translated in the London *Medical Record*, gives the latest improvements in his celebrated "bloodless" method of operating. He observed that it was now seven years since he brought under the notice of his colleagues his method of performing operations under the influence of artificial ischæmia. Since that time the great number of surgeons had tried this operative method, and there was reason to believe that some eminent and experienced persons who had employed it had abandoned it, wholly or in part, because they found that, after taking off the constricting band, the parenchymatous or secondary bleeding had been as abundant as with the old methods.

Esmarch regarded this as a fact to be regretted, for patients as well as for surgeons, since no one could deny the considerable advantages which ischæmia afforded during surgical proceedings. He asserted that the want of success attributed to ischæmia depended only upon the defective mode of employing it, and that the modifications which had been suggested on various sides were not of a character to reduce the number of failures. He had for several years continued to study the methods of obtaining bloodlessness during operations in his hospital practice, and of late years had succeeded in performing a great number of operations on the limbs without loss of blood, in the strictest sense of the word. He described his present mode of operating in three varieties of great operations performed on the limbs, in amputation, in resection, and in extraction of sequestra. In amputation, his rule was that, after performing the operation without loss of blood, he carefully tied all the vessels that were visible, but he did not immediately remove the constricting tube. He at once united the edges of the wound by the deep suture of Peltier, using catgut sutures. At the dependent part of the wound he placed a short drainage-tube, of material capable of absorption, and in cases of need caused it to emerge through an opening made in the skin. Finally, retentive dressing was then applied, and the limb was placed in a vertical position; then only was the compressing tube removed. The patient was carried to his bed, and so placed that, for half an hour afterwards, the stump remained directed upward and only at the end of that time was it laid horizontally. He had recently performed in this way twelve amputations—one of the forearm, one of the arm, nine of the leg, and a partial amputation of the foot—by Lisfranc's method.

In none of these cases did any consecutive hemorrhage occur; so much so that the dressing was left intact up to the fourteenth day, when it was removed. There was found only a narrow red streak stained with dry blood, corresponding to the cicatricial line. In resections he had, from 1873 to 1875, applied the dressing before the removal of the constricting tube, but he had observed secondary hemorrhages in consequence of insufficient compression; and he therefore abandoned this proceeding. From 1875 to 1878 he removed the tube before dressing, and performed the dressing only after having arrested all flow of blood. For the last two years, after having improved the mode of dressing, he had again endeavored to apply the dressing before removing the constricting tube, and he now proceeded in the following manner. After the operation, he tied the vessels which could be discovered. The edges of the wound were united by Peltier's suture, performed deeply with catgut, drains of absorbent material were introduced into the wound in a proper manner, and the final compressing bandage was applied. The whole limb was placed vertically, and the constricting tube was then removed. The limb in this position was secured on a splint with the aid of a bandage, and the patient was carried back in this position to bed; and not until half an hour afterwards was the limb placed in a more horizontal position. Since 1878 he had performed in this way fifty-six resections of the knee, the elbow, the tibio-tarsal articulation, and the radio-carpal articulation. In no case had secondary hemorrhage or death occurred. In thirty-three cases the dressing was left in place for three or four weeks; the progress of the wound was absolutely antiseptic. In cases of gouging, or of extraction of sequestra, the dressing was performed in the manner indicated by Esmarch some years ago; that is to say, the excavations of the bones were solidly plugged at first with carbolized cotton, and the end covered with salicylic acid dressing, and the whole firmly bandaged before removing the constricting tube. In 148 cases operated upon in this manner secondary hemorrhage followed, which passed through the dressing and made it necessary to renew it. In some cases, the compression of the bandage produced sloughing of the skin. In spite of these accidents, healing took place by granulation without abundant suppuration, but somewhat slowly. After disinfection of the cavity of the bone, carefully made with a solution of carbolic acid and chloride of zinc, the edges were brought firmly together by a catgut suture, absorbent drainage-tubes were employed, and the tube was not taken off until after the completion of the dressing. This method had been applied twelve times, and always with success. In no case did the escape of blood occur to such an extent as to make it necessary to renew the dressing. The wounds remained antiseptic. In the cure obtained by the first intention, the blood-clot, which fitted the whole osseous excavation, became organized in the way often described by Lister, and with enormous advantage to the patient—in reference especially to the rapidity of cure. The same dressing was applied in the same manner in other operations of extirpation of tumors, stretching of nerves, etc.; and Esmarch believed that this mode of procedure might ultimately be applied to amputation of the thigh and exarticulation of the hip and shoulders.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The Pittsburgh *Medical Journal* and the *International Journal of Medicine and Surgery* (New York City), are new ventures on the sea of medical journals, with the incoming year. Both are edited by a combination of medical men, whose names are a sufficient guarantee that honest work will be found in them. The last mentioned is a transformation of the *International Surgical Record*, and makes a specialty of translations.

——The Annual Report of the Board of Health of the City of Pittsburgh, for 1879, is a very well prepared document, with maps and plans. It has an interesting special report on an epidemic of typhoid fever which appeared in the city during the year, attributable to bad water, etc. The

committee also noted the prevalence of a disease simulating typhoid, but lacking the full character of that malady, a fact which has been observed elsewhere, and merits more attention than it has received. They say:—

We are inclined to the belief that simultaneously a large number of cases of illness occurred which we will, because of its lack of identity, and because of its similarity to typhoid fever, and finally, because we lack a more expressive or truthful term, designate as *pseudo-typhoid.* We belive these cases last mentioned may be honestly attributed to the use of the river water at that time, or to the use of water from wells which, while full of impurities derived from excreta, *i. e.*, cesspool sewage, yet lacked the presence of the specific typhoid germs.

Intestinal catarrh also prevailed.

——The Annual Address before the Alumni Society of the University of Pennsylvania was delivered, last spring, by Dr. Traill Green, and has appeared in pamphlet form. It was an able paper, full of thought and well worded. What he says of medical journals is most true, and we quote it:—

I doubt whether a number of any of them is ever read that does not furnish some useful hint to the practitioner who reads it; and in a consultation or an occasional conversation with a physician it is not difficult to determine whether he is in the habit of reading a medical journal, as much of treatment and the use of new remedies is learned from the journals before it is collected together in more permanent works.

——Dr. Boardman Reed, of Atlantic City, N. J., has given a condensed account of the merits of the climate of that part of the coast, in a recent reprint. He does not claim for it any special or peculiar powers, but only general hygienic advantages combined with accessibility. He observes:

After comparing my own experience with that of others, I am convinced that the atmosphere of Atlantic City in summer (perhaps also in winter, but I do not know) will prove especially beneficial in the large majority of cases of diseases of the respiratory organs, and that the very common opinion that the sea-coast is everywhere unsuitable for cases of phthisis has little foundation.

——Part XIII of Klein & Smith's "Atlas of Histology" treats of the outer and inner ear, the nasal mucous membrane, the spleen and ductless glands. This part completes the work, and a title-page, table of contents, list of plates, etc., are added. In taking leave of this work we wish to express ourselves with unqualified praise of the thorough work and high artistic skill evident in its production. There is no other work on histology which equals it. It is in every way equal to the demands of science in this field. (Published in London, by Smith, Elder & Co; in Philadelphia, by J. B. Lippincott & Co).

BOOK NOTICES.

Practical Taxidermy, and Home Decorations, together with General Information for Sportsmen. By Joseph H. Batty. 125 illustrations. New York: Orange Judd & Co., 1880. 1 vol., cloth, 8vo, pp. 203.

Mr. Batty has been official taxidermist to various government expeditions in the Western territories, and his experince in this and its kindred arts is, hence, unusually full.

After some preliminary chapters on outfit, camping, trapping, the choice and care of guns, etc., he describes how to prepare animals' skins for mounting, how to prepare and mount skeletons, how to collect, prepare and mount bird skins and eggs, the preservation of the reptiles, fish and crustacea, the making of cases, chests, cabinets and stands, and adds a number of recipes for cements, glues and preservative fluids. A second part is devoted to the decoration of homes with natural objects, such as ferns, autumn leaves, grasses, feather work, ornamental flower crosses, etc. The work is a praiseworthy one in all respects, and must certainly interest a large circle of readers.

We mention in this connection the beautiful illustrated catalogues of the Orange Judd Co. One is of rural books, the other of standard sporting books. They present a most tempting series of titles to the agriculturist, horseman, horticulturist, or sportsman, and if our readers want to be sure to spend some of their money, we advise them to write for these catalogues and look at their contents.

Transactions of the State Medical Society of Wisconsin, 1880, pp. 207.

Proceedings of the Louisiana State Medical Association, 1880, pp. 111.

The Wisconsin Transactions contain some papers showing close study. That by Dr. N. Senn, on fracture of the rim of the acetabulum, is an able analysis of the reports of twenty-seven cases, supported by a series of experiments on the cadaver. Three cases of acute anterior polio-myelitis are well reported by Dr. J. Dorland. Dr. George Seiler writes an able defence of the method of delivery in pelves narrowed in the conjugate diameter, advocated by Profs. Schröder and Goodell. Dr. G. F. Hunt gives an extended

study of the forms and causes of uterine hemorrhage. Other articles are on internal hemorrhoids, by Dr. H. T. Godfrey; on the presentation of the funis, by Dr. J. G. Meachem, Jr.; on medullary cancer of the kidney, by Dr. Geo. M. Steele; diphtheria, by Dr. B. O. Reynolds, etc. The annual address, by Dr. J. G. Meachem, is entitled "Honor to Medical Men."

The Louisiana proceedings contain a number of addresses and reports, by appointment, principally of a local character. Dr. T. G. Richardson gives the particulars of fifty-three cases of hydrophobia occurring in Louisiana. Dr. A. B. Snell has a thoughtful paper on the conservative influence of disease, in which he advances many just reflections. A useful contribution to medical hydrology is made by Dr. A. W. de Roldes, in an article on the use of cold water and the cold douche in algid and choleriform pernicious fever. The discussion on morbus coxarius, at the International Medical Congress, in 1876, is acutely reviewed by Dr. M. Schuppert.

Rocky Mountain Health Resorts; An Analytical Study of High Altitudes in Relation to the Arrest of Chronic Pulmonary Disease. By Charles Denison, A.M., M.D. Second Edition. Boston: Houghton Mifflin & Co. Paper, pp. 192.

Dr. Denison naturally writes in favor of high altitudes as a resort for consumptives, as each writer resident at a health resort writes in favor and not against it. But it is fair to say that he does so from considerable observation, with a good discrimination, and with a strong backing of authorities who recommend altitudes from a study of results. Not every case is benefited; some are injured, and should be forbidden even to try the experiment (p. 140). It is a strong point, which Dr. Denison considers well established, that if taken early, a resort to high altitude gives, on the average, better results than do less positive climates or means of cure. About one-half the cases who came to Colorado in the second stage, reported themselves "much improved," after an average residence there of a year and nine months. This seems to us a very good showing, and we do not know what climate can do better.

In the Swiss and Tyrolese Alps, very elevated stations are patronized, both winter and summer, by consumptives, with advantage, and no doubt our elevated plains at the base of the Rocky mountains will soon become popular sanatoria for numbers of invalids. His book will be found an intelligent and reliable guide for them.

Camping in Colorado. With Suggestions to Gold Seekers, Tourists and Invalids. By S. Anna Gordon. New York: Authors' Publishing Co. 8vo, cloth, pp. 201. Price $1.00.

This neat volume, composed by the wife of a physician, portrays a journey over the great western plains to the popular resorts of the Rocky Mountains. The events of the tour are narrated in an agreeable manner, and that the writer is a close observer is evident in every page. A great deal of general information about the country, the people, and their mode of life, will be found.

One chapter is devoted to the climate of Colorado, as one suitable for pulmonary complaints. Here the authoress acknowledges the helping hand of her husband. That he should have seen fit to introduce a new variety of phthisis—"hepatic consumption"—might justly lay him open to criticism. But passing that by, we note he is by no means ecstatic about the Colorado climate. He reports the development both of phthisis and asthma in previously healthy persons in Colorado. He says: "Few persons with weak or diseased respiratory organs can bear the higher altitudes," (p. 75). Many are unable even to support the atmosphere of Denver. The benefit seems to be greatest in children and quite young patients.

The volume is neatly printed and bound, and gives one a very good idea of what such a journey has to offer—both its pleasures and its disagreeables, the latter by no means few.

Prevention and Cure of Chronic Consumption. By David Wark, M.D. Authors' Publishing Co., 1880. Cloth, pp. 108. Price 80 cts.

In this small volume the author advocates a system of passive movements, intended to develop the respiratory capacity, and thus lead to a better aeration of the blood, the absence of which he considers the cause of tubercle. The suggestion is by no means new, and it has been amply shown that although this treatment is a useful adjunct to other methods, it is by itself quite insufficient, and in every way inferior to free out-door exercise. The pathological acquirements of our author are indicated by his definition of tubercles; these, according to him, are "composed of particles of food which have failed to acquire life while undergoing the vital processes, because the person in whom they occur habitually breathed too little fresh air."

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE USE OF TOBACCO.

The last six months have given publicity to quite numerous contributions to the question of the injury wrought by the use of tobacco. Many of these articles arose from the publication, in the *Lancet*, of a letter from the late eminent Prof. Parkes, so well known from his writings on hygiene. In this letter he wrote as follows:—

"As to the effect on the young, even, it is curious, in Burmah, to see children smoking in their mothers' arms; and yet when I was serving in Burmah, many years ago, I often saw a woman walking along smoking her cigar of tobacco rolled up in a plantain-leaf, and carrying on her hip her child of two or three years old, who also had his or her little cigar, which was smoked with the greatest gravity. On talking to the Burmese (who smoke constantly), they would never allow that even children were in the least damaged. When I was in Turkey I tried to make inquiries of some of the intelligent Turkish gentlemen; one or two of them said they thought the Turks had learned to smoke from the Europeans, and had been growing apathetic and dull ever since. But others laughed at this, and the rural Turk, who smokes a good deal, is a fine, active, energetic fellow.

"I have talked to many Germans, who all stand out manfully for tobacco.

"In conclusion, I confess myself quite uncertain. I can find nothing like good evidence in books; too often a foregone conclusion, without any evidence to back it, is given.

"I think we must decidedly admit injury from excess; from moderate use I can see no harm, except it may be in youth."

Such an admission, from so eminent an authority, naturally excited, in no slight degree, the ire of the tobacco phobes. Cases of paralysis and convulsions, chronic dyspepsia, amaurosis and other ills and ails, were sent in, to such an extent that the moderate smoker might well become alarmed. One suggests that the Life Insurance Companies should schedule separately their tobacco users from those who shun the weed; while another proposes that some half-a-dozen gentlemen in good professional practice should be asked to institute an inquiry among their paralytic patients, so as to ascertain whether smoking had anything to do with inducing paralysis, and for that purpose to inquire whether the parties had been smokers of pipes or cigars, and to what extent; and if smokers of pipes, what sort of pipe. Likewise to inquire whether paralysis was more frequent among men than women, or more severe in the one than the other.

With many the question is evidently already disposed of. One such breaks forth in this strain:—

"Eminent authorities, in every country and in every department of science, concur in classing tobacco among the narcotic poisons, than which none are more deadly; indeed, like Aaron's rod, it has secure within itself the most magical and worst of all its rivals—nicotia, sulphureted hydrogen, hydrocyanic acid! What a den of deadliest poisons, all having their *habitat* in this colossal curse, termed tobacco."

Evidently, to such a mind future investigation can offer no evidence worth the naming.

The net result of the discussion, so far as we can see, is like that of most desultory arguments; isolated facts are stated, but no general truth is educed. It is brought into stronger relief, that on some constitutions the effect of even small quantities of the weed is noxious in the extreme; that some persons can use it freely during a long life, without perceptible bad effect; while with the majority the moderate employment of it appears to exert, as Dr. Parkes said, no positive

toxic effect that we can unmistakably trace to this source.

The forms in which it is used have come in for a share of the discussion. One writer was of opinion that smoking a pipe is the least injurious, which is certainly contrary to the general opinion. The cigar, at any rate, is rapidly supplanting the pipe in civilized society. Snuffing, which was so fashionable a hundred years ago, and was probably less hurtful than smoking, has gone out of date in the better circles.

The whole subject is evidently one which could be advantageously studied again, provided the investigator divested himself of all partiality for or prejudice against the habit. For a long time we have had no report on the weed, of the author of which this can be said.

If we are willing to accept the opinions which sanitarians in other nations have formed, we have a very decided one ready to our hand in Switzerland. That intelligent republic enacted a law, last year, prohibiting the sale of tobacco to minors under fifteen years of age, and making it an offence against the law for such to smoke. Hence a boy of twelve or fourteen who parades the streets of Geneva or Bern with a cigar in his mouth is liable to be arrested and committed to the police station; and as they have a disagreeable habit in that republic of enforcing the laws they enact, such would be pretty certain to be the juvenile smoker's fate.

We recommend to our fellow-countrymen their manner of dealing with the habit, which, whether harmless or not to most adults, is unquestionably of great injury to young boys.

Notes and Comments.

Complicated Presentation.—Spontaneous Delivery.

M. Tarnier, in a recent séance of the Academie de Medéciné, of Paris, presented an observation by M. Queirel, of Marseilles. It was the woman's fifth pregnancy, all the others having been regular; in this labor it was found that the head presented in the third position, while at the same time both feet presented with the head. The contractions of the uterus were of great energy, and the child was expelled in this doubled-up position, and, astonishing to say, living.

M. Tarnier rather deprecated the inactivity of M. Queirel, in allowing such a labor to proceed without intervention, as craniotomy generally has to be performed when the presenting parts become engaged in the pelvis.

In such cases, before the parts become engaged the feet should be pushed back, if possible, and if not, podalic version should be performed, and the child extracted, instead of allowing the labor to go on, for the chances of a safe delivery with such a complicated presentation, are more than problematic.

Excoriations and Fissures of the Nipple.

Prof. Gio. Simula, 1880, Sassari, in a memoir on this subject, establishes the frequency of such troubles; 30 per cent. of nursing women being affected, according to Hinkel, 20 per cent. according to Schraden.

The nipples, are ordinarily affected in the first days of nursing, but rarely later on.

The causes are generally want of cleanliness, aphthæ in the mouth of the children, and the continual suction, which acts, says Joulin, like permanent cupping; the nursing of a child several months old sometimes induces these troubles. The accidents are of gravity, or not, according to the intensity of the inflammation.

The pain may be so excessive as to induce convulsions; the inflammation may extend to the mammary gland itself, whence abscess in this organ is accompanied by high fever. The nipple may be completely destroyed, and the resulting cicatrization prevent nursing thereafter from that breast.

As preventive treatment, Professor Simula prefers lotions of pure water to the astringent washes recommended by Trousseau and Cazeaux, which, in the end, he is persuaded cause the exfoliation of the epidermis. Against fissures of the nipple he recommends lotions of glycerine in a solution of bicarbonate of soda (Startin). He considers the application of compresses wetted in pure water, over the parts, as the best treatment in these affections, allowing the child to nurse as seldom as possible.

Antiseptic Dressings.

We have already given M. Champonnière' s methods of using simple solutions of carbolic acid: he resumes, in the *Journal de Med. et Chirurg., Prat.*, saying that salicylic acid cannot be depended on, and thymic acid is too caustic for

ordinary use. Nevertheless, the antiseptic of Pennès, diluted with water, may be used with advantage in the puerperal state. It is an acetic solution of carbolic acid, salicylic acid, and the essential oil of eucalyptus. This preparation is useful as a wash, but not in spray, as it is too irritating for the respiratory passages. As a topical application to wounds, carbolic acid, dissolved in olive oil, ten grams, and in a few rare cases twenty grams, of the acid to one hundred grams of the oil, can be very advantageously used, and, notwithstanding the large proportions of carbolic acid they contain, these solutions are not irritating; they may be directly employed, or the dressing may be saturated with them. Another excellent antiseptic topic is a solution of ten grams of carbolic acid in one hundred of glycerine. Whenever these solutions are used dressings should be covered with oiled silk, to prevent the volatilization of the carbolic acid. Sometimes such applications determine toxic symptoms, general malaise, gastric troubles, dark coloration of the urine. In such cases generally the liquid has been allowed to accumulate in the cavities of the wound, or there is a morbid susceptibility on the part of the patient to the action of carbolic acid; this is particularly true of children, and for them M. Champonnière has found it best to use boracic acid, which, though less powerful, is a good antiseptic. A saturated solution of boracic acid in water or glycerine may be employed as the carbolic acid solutions, but an ointment containing—

℞.	Ac. boracic,	20 grams
	Ung. petrol.,	100 grams.

will be found of very great benefit when applied to excoriated and burned surfaces, or where there exists ulceration, after an attack of impetigo or eczema.

But there are other antiseptic substances employed by the older surgeons—alum, tannin, sulphate of zinc—which may yet be used with advantage. Turpentine and all the resins and tar are excellent antiseptics. All these substances were formerly used. What characterizes their use in modern surgery is, exact knowledge as regards their power, in destroying germs and their methodic employment.

Treatment of Eczema of the Fingers.

In the Dublin *Journal of Medical Science*, Dr. Finny divides the treatment into four heads:—1. Internal medication; 2. Diet; 3. Washing; 4. Local treatment. Eczematous parts are, as a rule, too often washed. Instead of soap, he recommends oatmeal tea, or rain or soft water, with the addition of one tablespoonful of glycerine and two of finely powdered starch to the pint. In the early and acute stage soothing measures and ointments must be employed. When induration exists he finds india-rubber finger-stalls, fitting moderately closely, to cause rapid improvement; but these may make the finger hot and throb, hence many refuse to persevere in their use. For the itching he finds the following ointment answer well:—

℞	Ung. aq. ros.,	ʒ j
	Ung. picis,	ʒ iij–ʒ vj
	Zinc. oxid.,	ʒ ij
	Hydrarg. ammoniat.,	ʒ j
	Cosmoline, ad	ʒ ij.

Ft. Ung. M.

Testing for Sugar in the Urine.

In using Trommer's test, Salkowski, of Berlin, recommends that the urine should first be made alkaline by means of a solution of caustic soda, and that then the solution of sulphate of copper should be added, drop by drop, until, after strong agitation of the urine, a small quantity of the hydrated oxide of copper remains undissolved. The test used thus is very much more sensitive than by the ordinary method; but one must avoid boiling too long, as in that case a reduction takes place, even in normal urine, along with a separation of the yellow hydrated oxide of copper. For cases in which this test gives doubtful results Brücke's method is recommended, isolating the sugar and applying the fermentation test.

Special Reports.

IV.—PUBLIC HEALTH.

One of the most interesting recent contributions to this branch is a report on an investigation to determine the prevalence of

Adulteration in Food Supplies,

undertaken in accordance with instructions from the National Board of Health, by Dr. Smart. We shall give its principal results.

Tea.—Dr. Smart does not consider the so-called "facing" of teas with Prussian blue and silicates as injurious. Mixing teas is very common in this country, but is not harmful to health. His general results were as follows:—

The teas examined numbered 117, but of these two which were grown in Georgia, and six sent specially from Japan, may be excluded from present consideration. Of the 109 remaining, 90 were obtained from sources which presumably should have furnished a pure article, while 19 were purchased at such stores as might be ex-

pected to furnish an adulterated article, if adulteration was at all prevalent. In no case was a leaf observed which was not a true tea leaf. Of the 90 the only cases of debasement were those already mentioned as having probably originated before importation, while 5 of the 19 were so deteriorated that an analyst would have been warranted in reporting them as fraudulently adulterated—one, gunpowder (Y 2), from an excess of lime sulphate facing; one imperial (W 2), from admixture with sand, and three, imperials (Y 1, 2 and 3), from the presence of exhausted leaves. Whether these debasements were effected in China or in this country is an open question; but from the character of the English importations it is probable that exhausted leaves are dried and recolored in this country, for sale among the poorer classes of the community.

Coffee.—In this popular beverage something more positive was reported; but on the whole the examination did not yield serious results. The investigator says:—

Most of the dealers with whom I have conversed have been strong in their belief that adulterated coffee is not to be found in this country, as the beans are either home ground or ground by the supplying grocer. The results of H. B. Hill's examination for the State Board of Health of Massachusetts sustains this opinion, as ten samples of ground coffee, obtained in bulk, were found to be pure, while seven package samples consisted of one with no coffee, two with very little, and four with from fifty to seventy per cent. of coffee, the rest being roasted wheat, peas, beans and chicory. But the supplying grocer is not to be trusted in all cases, as out of the few purchased samples of loose ground coffee which have been examined during the present investigation, one contained a small percentage of chicory, while two consisted largely of chicory and roasted beans. Only one sample of package coffee was received, and it sustained the accuracy of Dr. Hill's results. Chicory, corn, wheat and rye were noted on the microscopic field as adulterants; but adulterants of what? for no coffee had been discovered, and half a dozen successive slides carefully examined failed to show the presence of the nominal article.

Three extracts or essences of coffee were examined, one of which consisted of chicory and the two others of roasted starches. Two of these bore on the label an offer of a reward for proof that any other extract of coffee was as pure as they, which does not say much in a general way for the purity of extract of coffee. Two samples of chicory were examined, both of which were found pure.

Sugar.—Cane sugar seems widely adulterated by glucose manufactured from starch. On this point the result was as follows:—

Among 47 brown sugars, most of which were furnished by dealers who knew that their samples would be examined, there were found 3 which contained glucose, while among 38 samples purchased for analysis no less than nine were thus adulterated. The glucose varied from a small admixture of 30 per cent. A remark by one of the dealers who furnished a 30 per cent. sugar is worthy of mention in this place: "*Oh!* they all have it, but they don't send any of it to *you*." Another storekeeper from whom a degraded sugar was obtained remarked, as he was putting up the samples, that I was welcome to anything he had, as he did not suppose he was any worse than his neighbors.

The white sugars, powdered, granulated, etc., were free from this adulteration; 24 of them were furnished by dealers and 15 were purchased. The syrups, of which 21 were sent in for examination and 12 purchased, were also pure.

Flour.—This important staple furnishes gratifying results. Of 58 samples examined, only one had any adulteration, and this was merely corn meal, probably introduced by accident. The same cannot be said of bread.

Bread.—Of 18 samples, 8 contained alum. Although it is by no means decided that the substance, as used by bakers, is hurtful, it is advised that it should be prohibited.

Cream of Tartar.—This substance is one of the articles which are subject to gross adulteration. Only eighteen samples were examined, but these were considered to be enough, in view of the character of the results. Six were of satisfactory purity. Eleven contained sulphate of lime, varying from seventeen to ninety per cent.; three having nearly the latter figure. Two contained no cream of tartar, but consisted instead, the one of sulphate of lime, alum, and acid phosphate of lime, and the other of alum, acid phosphate, and potato-starch. Corn-starch was also found in large proportion in one of the lime sulphate powders. Considering the use of cream of tartar in baking, its impure condition is a serious evil.

Baking Powders.—Contained alum and sulphate of lime, and were often decidedly impure.

Ground Pepper.—As ground spices in general are quite impure, Dr. Smart observes:—

The examination of the ground black peppers and spices shows to what extent adulteration may be practiced when its detection by the public is a matter of difficulty. The dealer himself appears to have lost the knowledge of the characters of the pure article, as out of four samples sent in by respectable houses in this city for the purpose of being examined only one was pure. The others contained baked flour and rice with sand enough to prove the unclean condition of the pepper itself.

Out of 18 samples of ground cayenne pepper only two were pure. Out of 23 specimens of commercial ground mustard 21 were adulterated. Out of 26 samples of ground cinnamon only *one* was the genuine article! The usual adulterants

are colored clays, roasted wheat, beans, rice, sawdust, etc., but, fortunately, no red lead.

In confectionery the red colors are generally harmless cochineal, but the yellows are often from salts of lead. Some yellow lemon balls yielded 7 grains of lead chromate to the pound of candy.

Relations of Epidemics.

At one of the meetings of the Epidemiological Society of London, last year, Dr. Longstaff read a paper on the relationship prevailing between scarlatina, puerperal fever, erysipelas, and other diseases, in which he deducted from the comparative death-rate curves and their annual fluctuations that the different causes of death should be classified into the *diarrhœal group*, relating to the heat of summer; the *bronchitic*, to the cold of winter; the *scarlatinal* group, and a provisional group comprising all the other causes of death not known to be much influenced by meteorological conditions. One object of the paper was to suggest the probability that the poisons of erysipelas and puerperal fever are identical, while diphtheria and croup are also due to but one poison, and to discourage the multiplication of species in the classification of disease. The paper was a valuable contribution to statistical medicine—a mode of studying disease which, pursued on an extended scale, enables the inquirer to arrive, by the numerical method, at the nature of the laws which regulate and govern the origin and diffusion of the disease. It had also bearings on the origin of diseases in zymotic or chemical poisons—now certainly one of the "burning" questions of the day in the medical world.

Impure Drinking Water.

A meritorious crusade is made by the *Sanitary Engineer* (New York city), against the scandalous and increasing depravation of drinking water in this country, by the multiplication of factories which let their waste flow into streams, and similar causes. The *Engineer* properly remarks that "The questions connected with the pollution of the water supplies of our cities are fast becoming of great importance, and the day is not far distant when every State will be compelled to take such action as will prevent either individuals or corporations from discharging waste and foul products into running streams." The *Sanitary Engineer* has commenced publishing a series of papers upon impure water supplies, and it is certainly high time that the attention of the public is so called to this matter as to render such a public injury impossible in the future.

This problem is rendered, or is likely to be rendered, more difficult of solution by the expected diminution in the rainfall in this country, owing to the cutting down of the forests. That some change in this respect has taken place seems certain. Mr. Ashbel Welch, Vice President of the Society of Civil Engineers, thinks that the tendency of the improvement and clearing up of land in the water-shed of the Delaware river has been to diminish the dry weather flow, and to increase the volume of freshets; that is, that while the total annual volume of water might be unchanged, the distribution of it throughout the year had been materially altered during the last century. Such considerations have a direct relation to public health, and properly come as much within the province of a physician as of any professional man.

In this connection, we may refer to a well prepared article in the *Journal of the Franklin Institute*, January, 1881, by Mr. Reuben Haines. Among other matters, he touches upon the important question as to the significance of animalculæ in water.

The chief point to be considered is, what may be associated with these animalculæ and upon which they may feed, or in some way be the indication of its presence. Some of them, undoubtedly, live only in comparatively good water, in proof of which statement the reader is referred to the work of Dr. Macdonald on the microscopic analysis of water. Some of them require a polluted water, and one which contains sewage in not too great amount will often be crowded with some forms, as was the case with some of the London water, which in 1851, and for some years after, was taken from the river at the London bridges, where contamination with sewage was very great.

These animalculæ, therefore, may be an indication of organic filth in the water, and this filth may be excreted from the intestines of diseased people. The animalculæ themselves are probably no more injurious to a human being than raw oysters. In all probability they can be digested with equal rapidity, and there is, as far as we know, no possible way for them to get into the blood in a living state.

The Consumption of Diseased Meat.

A continued article on diseased meat and its consequences upon human health or happiness, written by Dr. Noah Cressy, of Hartford, has been appearing in the last two numbers of the *Journal of Comparative Medicine and Surgery*, (New York City). He justly remarks that some of the most dangerous diseased meat is the most inoffensive in appearance, and least liable, from its looks, to awaken suspicion. This is especially true of trichinous pork. On this meat he adds:—

Our only safety from the use of pork, which is always more or less liable to contain trichinæ, in any portion of the country, is thorough *cooking*. Salting and smoking, unless long continued, has but little effect upon the vitality of these parasites. Raw ham or sausage should never be allowed upon a sanitary bill of fare; and even boiled ham, when large and fashionably prepared, as seen in many of our eating saloons to-day, not unfrequently contains these living worms. Hence our lives may be prolonged and our health improved by more attention being given to the domestic duties of the household. Then will all meats be served upon our table in a manner both to nourish and promote our happiness.

He mentions the curious fact that "braxied" mutton—that is the flesh of a sheep that has died from the most virulent form of anthrax—is not only harmless, but is a favorite article of diet with many! The flesh of cattle which have died of pleuro-pneumonia or "lung plague" does not seem hurtful. He says:—

Our great dread of the extension of the lung plague is not on account of any infectious condition of the meat, for millions of those affected animals, according to Fleming, have been consumed as human food in various parts of the world, and no evil results have been known to follow. In Great Britain and France there has been for years a regular trade with the butchers in cattle affected with the contagious form of this disease, and yet the sanitary condition of the people remains unimpaired. But it is the immense loss to our live stock property that would be entailed by such a calamity.

Nevertheless, we presume the public would be better satisfied in mind to consume flesh of healthy animals, if the choice was given.

Correspondence.

Observations at Hot Springs, Arkansas.

Ed. Med. and Surg. Reporter.

Although the literature upon these "wonderful" waters is by no means scanty, as standing articles extolling their virtues appear in both of the dailies issued here, and, thanks to the liberality of one of the resident physicians, pamphlets containing full information regarding their therapeutical value are distributed gratuitously all over the land, yet, I have thought it my duty to add my mite in the way of a few observations made during a two weeks' sojourn at this place.

Situated in a picturesque valley, surrounded by pine covered mountain ridges which, extending in various directions, give a characteristic grandeur to the scenery, that reminds the traveler of the dense pine forests of the Scandinavian peninsula, this famous health resort has many natural advantages that should not be overlooked. The climate is even and salubrious, the winters being usually mild, resembling spring in the North, though occasionally there are spells of severe cold, and since my arrival here the mercury has been down to 6° below zero, Fahr., and while the temperature in summer frequently runs up to 100° and more during the day, the nights are always cool and pleasant, and the atmosphere is rendered soft and balmy by the terebinthinous exhalations of the pine trees. The city, which numbers about 5000 inhabitants, extends over a considerable area, and consists chiefly of bath houses, hotels and boarding houses, gambling houses, doctor's offices, and brothels, none of which can lay any claim to architectural beauty, for with the exception of a few of the bath houses, that are fitted up in good style and provided with all modern luxuries, and one or two buildings under construction, nothing but miserable board shanties are to be seen anywhere. I must not forget to mention that an enterprising Chinaman has also opened a den, recently, for the accommodation of those addicted to the habit of opium smoking, many of whom come here to get cured of this vice. The streets and sidewalks are in a bad condition, and there is nothing to show for the vast amount of money spent here annually by visitors,* and the immense expense of the United States Government during the sojourn of her commissioners here.

Although the season has not commenced yet, one meets everywhere the lame and deformed, the miserable wretch whose nasal bones have disappeared and the victims of the worst forms of cutaneous diseases, all being here with the hope of getting cured, yet few having money enough to pay their physician, or even buy medicine, relying solely on the virtues of the waters, forgetting that the baths cost from $4.00 to $10.00 per course (21 baths). Thanks to the munificence of the United States government, the indigent may, however, bathe free, at the mud hole, after 6 P.M. The baths are usually taken at the temperature of 96° to 108° Fah., and the water drank at a much higher temperature—about 120°. Cold and warm douches, vapor baths and packs are also made use of, to great advantage, in certain forms of disease.

As regards the therapeutical effects of these waters, they have undoubtedly been over estimated by those who are pecuniarily interested in drawing visitors to the place; but judging from the large number of persons who have come here on crutches, the victims of rheumatism, and who are now enjoying perfect health, there can be no doubt of their potency in this affection. Their efficacy in the treatment of various forms of syphilis (when used in conjunction with mercurial inunction and large doses of iodide of potassium), is also a matter of every day observation here; but I am rather inclined to believe that this depends more on the eliminative effect of the hot water used, both internally and externally, enabling the patient to take anti-syphilitic remedies in much larger doses than could otherwise be borne, than on any specific virtue in the water, for, as Prof. Keyes, observes, "the water is cer-

* The number of visitors who annually resort to the Springs has been variously estimated; thus one of the daily papers gives it as 25,000; a physician here told me that 45,000 invalids visited the place last year, while the superintendent of the railroad said that the number did not exceed 1000.

tainly quite poor in mineral ingredients, while its alleged magnetic qualities are imponderable." Iodide of potassium is frequently given here in enormous quantities (an ounce and a half to two ounces daily), and mercury in proportionate doses, without producing any unpleasant symptoms whatever. One of the most marked effects produced by the use of these waters is a rise in the temperature, together with an increased activity of the circulation, and, of course, of tissue metamorphosis, the products of which are rapidly removed by the augmented action of the eliminative organs. Now, if the modern theory of the mechanical action of mercury be true, it is easy to comprehend how these waters may become useful as an adjuvant in the treatment of syphilis, especially in its later stages, when deposits have formed and nutrition is greatly impaired.

In such skin diseases as are not attended with active hyperæmia, the judicious application of these waters is often followed by excellent results, and patients suffering from an atonic condition of the nervous system, caused by over work, are invariably benefited here, while in all active congestions the waters are contra-indicated.

As some of my readers may desire to learn something of the standing of the medical profession at Hot Springs, I have taken great pains to ascertain how far the charges of unethical conduct preferred against most of them by their professional brethren abroad, and the ethical portion of the profession here, are founded on facts; and after careful inquiry I have been informed, by trustworthy, and disinterested parties, that up to within little more than a dozen years ago, when there was only one practitioner in the place, the violation of the code of ethics was never heard of. No sooner did, however, another Æsculapius appear upon the scene, than human nature asserted itself, an open rivalry arose as to who should control the practice of the place, in which the late arrival came out victorious, being a man of large means, which enabled him to buy the influence and good will of the principal hotels by putting $18,000 in the Arlington, $9,000 in the Grand Central, and $3,000 in the Continental, and having amassed a fortune he withdrew from the contest, selling out his practice to a couple of industrious young physicians, who have proved themselves his worthy successors.

Little by little a number of able and intelligent physicians were attracted to the Springs, many of whom came here for their own health, and finding it impossible to get a practice by legitimate means, as long as all the principal hotels acted as drummers for one medical firm, that wonderful production of American inventive genius, the commercial traveler, was taken into service and sent out upon the highways to bring in the cripple, the lame, and the blind; drumming became general; the practice of medicine at Hot Springs was from this moment established on a true commercial basis; the code of ethics became a thing of the past, a medical abortion, and, though constantly on the lips of a few of the "ethical" members of the profession here, it simply serves to tie the hands of the honest physician and let the quack loose. Attempts are, however, made to protect the unwary against the rapaciousness of the fierce and hungry wolves who infest the place; thus a philanthropic society has recently been formed by the oldest and best citizens, who have issued circulars and engaged the services of one of the most experinced drummers to distribute them among the passengers en route for this "world's sanitarium," giving them due warning to beware of quacks and cheap boarding houses, which may easily be avoided by proceeding directly to one of the principal hotels.

The agents of this society will also furnish a list of the reliable physicians in the place, or such a list may be had upon application at either of the bath houses or banks. Although it ill becomes me to interfere with so well-meant advice, yet I feel it my duty to state that board may be had here for from $4.00 a week to $1.00 day, and that the greatest comfort is usually to be secured for the smallest price, and though the bankers may be ever so reliable judges of who are the best doctors, I should be afraid to trust them with my money, lest I get back only 40 cents on the dollar, as was the experience of a large number of the visitors here in 1878. My advice to the invalid who comes here for his health is: Get a letter of introduction from your family doctor, or some one in whom you have confidence, to a physician here, and secure board and home comforts at a private house. To physicians who may desire to come here to practice their profession, let me say you have two courses to choose between: either establish your business on a fair and square up and up competitive plan, recognizing no other code than that which teaches "every man for himself and the devil for us all;" or if you value your professional standing, let the code of ethics, studied by the aid of that most valuable of all text books, "The Black Arts in Medicine," guide all your actions, and if you possess the necessary qualifications, a fair amount of brass and brains if you have plenty of the former article the latter may be dispensed with), a fine form, and an eloquent tongue speaking words of wisdom on all proper occasions, immeasurable success will be yours. It is also advisable for a new physician, in a place like this, to board at the best hotel, or should his purse not allow him to do so, let him eat at some cheap restaurant and at once proceed to the hotel and pick his teeth on the steps, where people will see him. Another ruse is to engage a number of loafers, whose services may be had for a song, to sit in the reception-room, personating patients, and if a real patient comes, let him wait a couple of hours before admitting him. Yours, truly,

JACK.

News and Miscellany.

Medical Society Items.

—At the approaching International Medical Congress in London, next summer, it has been decided that there shall be an international exhibition of medical and sanitary appliances of all kinds; and leave has already been granted for space for the purpose in the Exhibition Building at South Kensington. An active committee has

been formed to organize and manage the exhibition. It will contain all branches of hygiene and medicine, together with surgical appliances and apparatus in use in the sick-room and hospital. It cannot fail to create an interest beyond the limits of the profession. Considering the novelty of the undertaking, and the wide-spread interest associated with its objects, the exhibition cannot fail to command general approval and ultimate success. It is proposed to inaugurate the exhibition about the middle of July, and to keep it open during the month of August.

—The "American Surgical Society," though organized last June, has not come prominently before the public as yet. At the first meeting, in New York, about forty persons were present. A constitution and by-laws were adopted, and the following officers elected: Dr. Samuel D. Gross, Philadelphia, President; Dr. L. H. Dugos, of Augusta, Ga., and Dr. James R. Wood, of New York, Vice Presidents; Dr. John H. Packard, of Philadelphia, Treasurer; Dr. T. R. Weist, of Indiana, and Dr. W. T. Briggs, of Tennessee, Secretaries.

—A Congress of Laryngology is announced for September, 1882, in Paris. The members of the organizing committee nominated are MM. Fournier, Gougenheim, and Krishhaber.

—At the annual meeting of the Centre District, N. H., Medical Society, the following officers were elected: President, H. A. Weymouth, Andover; Vice President, George Cook, Concord; Secretary, George C. Blaisdell, Contoocook; Treasurer, M. W. Russell, Concord.

—At the Annual Meeting of the Northern Medical Society, of Philadelphia, held at their Hall, 14th inst., the following officers were elected for the year 1881: President, Dr. James B. Walker; Vice President, Dr. H. W. Rihl; Treasurer, Dr. E. E. Montgomery; Recording Secretary, J. G. Heilman; Corresponding Secretary, Dr. J. T. Eskridge; Reporting Secretary, Dr. L. B. Hall; Councillors, Drs. M. Hatfield, W. M. Welsh, R. J. Hess, E. R. Stone, L. B. Hall.

The University's New Provost.

Dr. William Pepper, who was recently elected by the Board of Trustees of the University of Pennsylvania, Provost of that institution, has sent to the Board the following letter of acceptance:—

Hon. John Welsh, Chairman: Dear Sir:—I had the honor of receiving, to-day, a sub-committee, composed of Messrs. Rogers, Merrick and Mitchell, who informed me of my unanimous election as Provost of the University of Pennsylvania.

They informed me at the same time that the Board of Trustees had made certain modifications in the duties and power of the Provost, and had also enlarged the disciplinary and supervising functions of the respective Faculties. While rejoicing at what appears a marked improvement in the organization of the University, I am highly gratified at finding that these changes render it possible for me, while continuing to hold my Chair in the Medical Department, and to pursue the practice of my profession, to accept the important post to which I have been elected.

I shall esteem it the highest honor and privilege to be able to serve the University in this capacity, and I earnestly trust that with the cordial coöperation of the Board of Trustees, and of the various Faculties, the general welfare, and the efficiency of its administration may continue unabated.

I have the honor to remain your obedient servant. WILLIAM PEPPER.

The National Board of Health.

It is a painful commentary on the woful ignorance of and prejudice against public medicine, which exists in this country, that the National Board of Health has had so lukewarm a support from the public press. It has even met with not a few violent attacks, as witness the following quotation from a prominent daily newspaper published in this city:—

"Beyond entering upon the publication of a superfluous newspaper, the National Board of Health has, so far, not been known to the public as undertaking any work of sufficient importance to justify its existence. Revived and established in its present form by the demand for some competent agency to deal with the yellow fever, when that disease threatened to spread over the country, in 1878, the Board was expected to supersede the local sanitary authorities generally, and to nationalize especially the quarantine service of our ports of entry. It was very soon found that this design was wholly impracticable. While no one will be disposed to prejudge the case, therefore, it may be fairly said that the Board will have to make out a better showing than has yet been accredited by the public, before an appeal to Congress for more money and more power will be likely to receive favor."

These statements are a tissue of errors. It was never intended that the Board should take the place of local Health Boards; the yellow fever is by no means the only foe it was framed to oppose. The *Bulletin* published by the Board is a publication of great and increasing value, recognized as such by all statisticians. There is not another civilized country that does not give more attention to, and spend more money in proportion on matters of public health than ourselves.

Curiosities of Vital Statistics.

In a recent lecture the Rev. J. A. Nutting, of Fall River, Mass., quoted a series of vital statistics, to show the relationship between the birth rate and the number of divorces. He said:—

During the past twenty-five years the birth rate has decreased about as fast as the divorce rate has increased, and where the birth rate is lowest—which is where Yankees most abound—the divorce rate is highest. There is a close connection between a low birth rate and a high divorce rate," expressing his belief that "the relation between the two is that of cause and effect, the former being the cause, and the latter the effect. In the history of nations there never has but three times occurred such a breaking up of the family as is now taking place among people of New England blood. When the Greek

and Roman empires were about to fall, and during the French Revolution of the last century, twenty thousand divorces were obtained in France in one and a half years. Bad as this is, when population is compared, it is not equal to what is true of Rhode Island and Connecticut of late years.

Without vouching for the entire correctness of these statements, we believe they are largely true, and their cause is not far to seek.

A Violent Listerian.

Professor Nussbaum, of Munich, is such a determined partisan of the antiseptic method, that he would extend the statute of the German penal code, dealing with bodily injuries and damage to health through negligence or malapraxis, to such a case as a surgeon examining a wound with a finger not disinfected according to the strictest antiseptic principles. He considers, also, that the duty of carrying out these principles excuses the medical man from making, in a medico-legal case, that thorough and searching examination of a wound formerly required.

Position of Resident Physician.

An examination for three resident physicians, for the Western Pennsylvania Hospital, to serve for one year from April 1st, 1881, will be held at the hospital building, Pittsburgh, Pennsylvania, on the fourth Wednesday of March, 1881, at ten o'clock, A.M. Competition open to all graduates in medicine. About 1000 patients treated annually. Clinical instruction given daily by the staff. By order of the staff. Examiners: Chas. Emmerline, M.D.; James McCann, M.D.; W. J. Asdale, M.D.

The City of Mexico as a Health Resort.

A private letter from Mexico, dated December 28th, says:

"This is the great health-resort of the country. You could not imagine a more equable climate. No hospital remains so nearly the same temperature. My thermometer was 61° this A.M. at eight o'clock, in my room, and 60° at the door. It has not been below 58 for several days, and not above 65, and I have seen it two or three times a day. To-day I rode to a great stone basin near the town, and had a glorious plunge in spring water from Chapultepec, in the open air. Yesterday I rode over the line of Cortez' entrance into the town—30 miles, in the middle of the day without feeling the heat. Sunshine is continuous. The spring leaves are pushing, the almonds and oranges are in bloom. The roadsides are lined with scarlet sage, and I can buy a dozen roses for a farthing."

Bills Presented.

Those subscribers who have not as yet remitted for the REPORTER, for the present year, will find their bills inclosed in the present number. Their prompt attention to them will greatly oblige the publisher. Such little matters, if deferred, are very apt to be forgotten.

Items.

—Dr. Livingstone's case of surgical instruments, which he carried through Central Africa, until his death, has lately been exhibited in a shop window in Glasgow, and attracted great public attention.

—In Providence, Rhode Island, last year, there were 276 persons who died over 70 years of age. They were in the proportion of 42 males to 58 females. The two oldest were both 99 years, but as both of these were natives of Ireland, where positive proof of age is not obtainable, some doubt rests on their ages.

—Nothing is so much to be deprecated as too much zeal in a good cause. Hence, we cannot applaud the action of the curé of Scudoni, Spain. He is an opponent of homœopathy, and has declared that any sick person belonging to his parish who has tried to cure himself by the system will, in the event of death, be refused the rites of the Church.

QUERIES AND REPLIES.

J. G., Jr., of Ala., asks: "Will not chlorate of potash and calomel, when given together, form the bichloride of mercury?

Ans.—The assertion that calomel is changed into corrosive sublimate by the chlorides of the alkalifiable metals has been asserted and denied. As a laboratory experiment it is true, but certainly to a much less degree as a clinical fact.

Dr. H. L. C. asks for suggestions in an obstinate case of *Eczema rubrum.*

Ans.—After the usual preliminaries of washing, removing scabs, etc., the following is used in the British Hospital for Skin Diseases:

℞.	Zinci oleatis,	ʒij	
	Adipis,	ʒj	M.

Much depends on general, constitutional treatment and hygiene. The tar preparations and the alkalies we suppose have been tried.

Dr. Ledgard.—If there is any depilatory the use of which is efficient, and free from pretty serious objections, we do not know it. Removing the hair by electro-puncture has not proved satisfactory.

Dr. K. P., of Ill.—St. Anthony's fire is generally applied to herpes zoster or zona; at times, also, to erysipelas. "Hives" is usually urticaria: sometimes herpes. Such popular terms, of course, have no exact meaning.

MARRIAGES.

BECKWITH—HUNTER.—In New York, on Thursday, January 13th, by the Rev. Thomas S. Hastings, D.D., Frank E. Beckwith, M.D., and Miss Rachael B. Hunter.

BROWN—BOSWORTH.—In Lebanon, Vt., December 29th, by the Rev. J. M. Dutton, assisted by the Rev. J. E. Robbins, Dr. Frederick H. Brown and Alice Bosworth, both of Lebanon.

DEATHS.

CAREY.—In Fincastle, Ohio, on December 17th, at his residence, of paralysis, Dr. S. E. Carey, aged sixty years and four months.

DEYO.—At Newburg, New York, on the 21st inst., Nathaniel Deyo, M.D., in the sixty-fourth year of his age.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O	
Quinidia do	15 "	20	24	2	2	
Cinchonidia do	15 "	C	H	N	O	
Cinchonia do	15 "	20	24	2		
Chinoidine Purified,	30 "					

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

MALARIA.

BY T. S. BELL, M.D.,

Professor of the Science and Practice of Medicine in the University of Kentucky, at Louisville.

Reported for the Medical and Surgical Reporter. BY A. H. KELCH, M.D.

Gentlemen:—I wish to call your attention this morning to well ascertained truths. I show you, here, Johnson's Atlas of Physical Geography. We learn from the Epidemiological Society, of Edinburg, that from the equatorial line of maximum temperature, to the 23° of north latitude, the average mortality from one cause is fifty-three per cent. In latitude 35° north, with isotherm in July 77° near the boundary line of the other zone, the mortality from this cause is fourteen per cent., and in this domain are located many of the largest cities of the earth. In latitude 35° south the mortality from this cause is but three per cent. Now, if we look into this subject, we may get some facts for our consideration. In the first place, in this region of a mortality of fifty-three per cent. from that cause alone, we find seventy-five per cent. of that fifty-three per cent. due to yellow fever, cholera, tropical dysentery, and other malarial fevers. We find there is over this area a combination of temperature, aqueous deposit and vegetable growth; and this combination of conditions is adequate to the production of the effects I have named, while either of them alone would be insufficient. In the beginning of this century the people of Germany were perfectly astounded by the presence in their midst of a dysentery, that swept off thousands of people, and it even extended to Göttingen. There were large districts among the places assailed in which the disease did not prevail. A distinguished German physician who wrote an account of that endemic, when he spoke of the solar temperature, said there was in Germany the heat of Calcutta. What is it that gives to the Cape of Good Hope and all that region south of the thirty-fifth parallel south latitude an entire immunity from these devastating diseases? Everywhere in that region, though the temperature may run very high, there is very little rainfall. This, therefore, has something to do with the presence or absence of this poison. Then, again, I call attention to the fact that there are in Asia 4,000,000 of square miles where the solar temperature is abundantly high for the production of this poison, where none of its effects have been known to occur. At the lower border of this 4,000,000 of square miles are situated the cities of Bagdad and Bassorah, and here we have an immense amount of vegetable growth, which decomposes, in addition to the filth generated by the dense population, and moreover, the water must be kept out by dykes. At these points the virulence and activity of the poison are too well known to need comment.

Let us look nearer home. Suppose you travel in Kentucky, and reaching Shelby county stop to visit a friend. You find that friend and all his family pictures of perfect health. You find them preparing to attend a funeral at a house which you can see very plainly on the opposite side of the sluggish creek, between the two places, and you perceive that the creek is much nearer to the

house of your friend than that of his less fortunate neighbor. Your friend has resided in his present situation from early childhood, and he and his family have been exempt from these forms of disease I have mentioned, while every year the place on the opposite side of the stream has been visited by disease, if not death, these visitations occurring very generally in the spring, summer and autumn.

Let us suppose another case; that you travel in Virginia, in the neighborhood of Petersburg and Richmond, and there you find a farm that has been celebrated for nearly two centuries for the perfection of healthy conditions. To it the wealthy citizens of Petersburg and Richmond were accustomed to resort during the heats of summer, to enjoy its pure, fresh atmosphere, and revel in the delights of a wholesome rural life. In order to utilize all the benefits of this situation, it was determined to build an immense mansion house here. This was done; it was filled with occupants, and the summer passed to the entire satisfaction of those who had resided there. The next summer the same thing was repeated, and with like results, until all began to think that at last a perfect health resort had been found. The third summer they went again, when in a single night every person in one end of the building, on one floor, was taken violently ill, many with vomiting, others with purging, and still others with chills. They were perfectly astounded. In all their previous experience nothing of this kind had occurred. They set themselves to the task of determining the cause of this attack. It was known there was no marsh in the community, and, in fact, the entire region seemed to be free from everything that could produce such a calamity. They were struck by the fact that there was a long row of negro cabins running at right angles to the wing of the house, and the occupants of these were entirely exempt from any disease whatever. They moved the inmates of that part of the establishment into the cabins, and then they began to inquire, why is it that only the inmates of one wing of this building, and of only one floor, were attacked. The inquiry and investigation went on, until some one thought of going into the cellar. There they found an immense amount of rubbish, which the carpenters had thrown there, and in addition a large number of bundles of shingles left over from the roof, and these all in a state of decay. There was no such rubbish in the cellar of the other wing. The place was cleaned and dried, and sickness ceased. Does not that indicate something?

Dr. Wootten, one of the most accomplished physicians of the State of Alabama, was summoned one morning, in great haste, to a plantation a few miles from Mobile, to see the negroes, who were all ill. When he arrived he found—what he had often seen before—a sluggish stream, running through a very fertile piece of land. It very often overflowed its banks, inundating the rich land covered with vegetable growth, yet the inhabitants had not suffered. Why should this change occur this season? A portion of the land between the huts and the stream, that had previously been covered with trees, had been brought under cultivation. Dr. Wootten made the proposition to have them all conveyed to the opposite side of the stream; when this was done they all recovered.

Let us suppose you meet Dr. Robinson in Manchester, in England, and in conversation with him you learn that on one occasion a vessel came into Liverpool, touched at one of the wharves, and that in the night every seaman on that side next to the wharf was attacked with violent cholera; not a case on the opposite side of the ship. The vessel was warped out to sea immediately after such unfortunate occurrence, and the sickness ceased. Late in the afternoon of the following day, another vessel from a distant port, the sailors knowing nothing of this occurrence, takes position at the same place, and meets with the same misfortune.

Now what is this enemy to human life and health; what is its character? It eludes every one of your senses. It does not address itself to your nostrils, your eyes, your ears, nor your taste. It is a silent, quiet enemy, that has devastated countries and cities. Our country is an example of it. It has, within the last fifty years, been the terror and the pest of the farmers and planters about the junction of the Alabama and Tombigbee rivers. They have even been compelled to desert their farms and plantations. Now, gentlemen, if you study the manifestations of this poison you may be able to determine that it appears most active and virulent in the neighborhood of a sluggish stream or marsh. You go so far as to observe that it only acts in one direction every night, and that, therefore, those who happen to be in that part will be attacked, while others out of it are not. You have gathered one or two interesting facts concerning it; but do not rest there, in the imagination that you have conquered the enemy.

There is in Gascony, France, an immense region covered with white sand washed up by the sea, and it is so deep that the people go about

upon stilts, which they have learned to do quite skillfully. For a long time the French Academy was very much astonished to find some of the worst forms of remittent and intermittent fevers in France about this spot. There was not a drop of water near it at this season, there was no marsh near it. Now this throws you all aback. You have satisfied yourself before that you have the solution of the case in the sluggish stream or a marsh, and you may be correct in that finding, but how are you to solve this case where there is no sign of a marsh or stream. When Julius Cæsar first visited it there were immense groves of olive trees growing there. These have all been removed and the sea has washed the sand all over this region and there is no living vegetation within it. I shall refer to this subject again presently.

Again, let us come nearer home. In 1850, on the 24th of July, between Tenth and Eleventh streets, in this city, an endemic cholera appeared. I was sent for, about 9 o'clock at night, and the messenger brought the information to me that there were then thirty bodies of those who had already died there, and that about twenty more would undoubtedly be dead before morning, and at that time this portion of the city was comparatively thinly populated. Now think of fifty people being thus destroyed, in so short a space of time. This began in the night, and on the next day there was not a single attack as long as the sun shone, but very soon after sunset there were fifteen new cases; and these, too, were cases of as deadly a disease as ever occurred upon the earth. These cases were attended by the ablest physicians of Louisville, and many of them were prescribed for at the very moment the first sign of sickness appeared. There was not a single individual of the whole number in any way benefited or improved by the medication.

There was a row of houses that extended from the southeast corner of Eleventh and Market, up half way to Jefferson, the lower floors of which were below the sidewalk. Immediately opposite, on the northwest corner, there was an old pond in connection with a hemp factory, and into this pond had been thrown the refuse matter until it came above the surface of the water, and absorbed it. It had been covered over with a thin surface soil, which at this season of the year appeared as dry as this floor. Upon a careful examination, with a view to determining the cause of this trouble, the apparent dryness we found to be far from real. Our walking sticks, when made to penetrate it, caused the water to ooze up around them, as if the ground was spongy, and filled with water. We next examined Tenth street sewer, which was designed to drain this region, and this was found totally choked. These conditions were speedily removed, and nothing of the kind has ever been known since, though at that spot there live now twenty people to where one lived then. When you come to practice medicine, gentlemen, it will be demanded of you to investigate such questions as this. and you must understand them thoroughly, if you would hold your place in public esteem. It is incumbent upon you that you be able to investigate, and remove conditions tending to the death of individuals in your community.

Let us now return to the subject of the sandy district I have previously spoken of. A distinguished gentleman from the French Academy of Medicine was sent down there to determine the cause of this fatal sickness reigning there. After many other investigations were made he finally bored down in the sand until he came to what gardeners call "hard pan," a layer so hard and solid that it does not permit water to pass through it. As soon as his auger struck that it showed immense quantities of vegetable material washed down through the sand; and that was the case all over this region of sand, wherever these intermittent and remittent fevers were so prevalent. The rains of the winter soaked down to this, and in the summer the solar heat brought about that condition necessary for the development of this poison by decay.

On the second day after the pestilence broke out at this place, we moved everybody out, not permitting any one to sleep there. The injunction was given those who remained to minister to the wants of the sick, not to sleep, not even five minutes. Heeding this injunction, after this frightful mortality not a single individual engaged in the care of the sick suffered any inconvenience. How were they protected? No medication was addressed to them, nothing but their abstention from sleep saved them. How do we know that? We will see. There was an old lady visiting there, who knew nothing of the warning about sleeping there, on Monday night, and on Tuesday she went home, where she remained in perfect health for three weeks. On the twenty-first day after she had slept there she was taken precisely as those who were affected on Monday night. She died in just about the same number of hours, in the same way, and there was not another case of that sickness in Jefferson county. What are we taught by this? She had been where the cause was, and she had

acquired that cause in a sufficiently potential form to destroy her life, though it seemed to have remained latent for a time.

A young man who had been boarding in one of these houses at the time the calamity occurred escaped for the time being, and went to Preston street. Between three and four weeks after he was attacked in the same way the others had been, and he died in just the same manner, and he was the only individual on the street thus affected. Had he removed before the calamity occurred, and not slept in that locality, he would probably have escaped. He might have slept there all day with immunity, but five minutes' sleep after sunset, when the dew point is reached, is sufficient to decide a fatal destiny. These two individuals I have mentioned were the only ones in their locality who had anything like the disease. A man with his entire family moved from this district to Oldham county on the next day. He called to see me a few days afterwards, to determine if it would be safe to go back there. I found he had slept there, and I asked him if he had done anything for himself and family. He replied he had not. I feared it was then too late. I advised him, however, to take some salts of Peruvian bark as quickly as possible. He did not deem it advisable, as he, and all his family felt well. The advice was superfluous, as the next morning every one of the family was dead. The period had come for this latent cause to become a very active one. Those whom we moved were taken to the city hospital, and every man, woman and child was given the salts of Peruvian bark, and of all that number not a single one showed the slightest evidence of the disease. A Baptist minister, who had lost the whole of his family in the first onslaught, came to see me the next morning, to ascertain whether he could do anything to protect himself from the misfortune his family had suffered. I told him to take ten grains of quinine every two hours, until he was thoroughly under its influence, and to keep himself in that condition for two or three weeks. He did so, and was alive years afterward.

Some of you may travel in Italy after awhile, and when you reach Rome, a short time after sunset, you will find every gate is closed on the west side. You inquire the meaning of this, and you are told that the Campagna di Roma is a very fatal spot. You call up your history, and discover that in the time of Augustus Cæsar that was said to be the garden spot of the earth. At that time Rome did not close her gates on that side at sunset. At the time when the Goths and Vandals invaded Rome, they converted this beautiful spectacle into a desert, and now, no mortal man dares sleep there a single night.

Go back to Florence, that beautiful city of flowers, and from the tower of the Cathedral, in former times, you could have seen, shortly after a few strokes of the bell, 100,000 armed men marching through the streets of the city; you look down the beautiful valley of the Arno, until it looks like a distant thread of silver, winding its way among the cultivated fields that border its banks; and in all this region you will find that not a single inhabitant attempted to stay there at night after the latter days of June, until November. Along the Mediterranean coast the inhabitants built watch towers for the use of those who guarded their property while the terrific strength of this poison kept them away from it. These watchmen alternate with each other at night. If they keep awake until they get up to the top of the tower they are safe. It is an interesting fact that these people have no difficulty in employing watchmen to attend these places, so well do they understand the conditions of existence there. But a mighty change has been effected here. The subject of that change will engage our attention at the next lecture.

Communications.

CLINICAL STUDIES OF INEBRIETY. THE TREATMENT OF INEBRIETY EMPIRICALLY.

BY T. D. CROTHERS, M.D.,
Superintendent Walnut Hill Asylum, Hartford, Conn.

Some years ago I was informed by a physician that the treatment of inebriety was most successful when the patient was given alcohol in all his food and drink, until both body and mind repelled it, or he was so thoroughly disgusted as to be forever weaned from it. Later, when I began to study this subject, and became connected with an asylum for this class, I was surprised not to find, or hear of any one who had seen this theory put into practical operation. Friends of patients frequently inquire if this was not the means used in the treatment, and when questioned could give no authority for their belief. For years I have occasionally noticed statements of this plan of treatment, in both the secular and medical journals, and made many inquiries as to its origin, without finding any intelligent answer. An editor of a medical journal wrote an editorial on this subject some years ago, which, from inquiry, I found to be based entirely on the supposition that such a plan of

treatment had been tested frequently in both hospital and private practice. A physician in Ohio wrote me that a lady in his neighborhood had attempted this plan of treatment with her inebriate husband, which resulted in developing a furious mania, five days after, and his commitment to an insane asylum as a dangerous person.

Dr. Beike, a Swedish physician, gave me the following account of the only test of this plan of treatment which I have been able to find, and which I think is the foundation for all the stories of this theory that have appeared. In 1856, a clergyman in Stockholm, Sweden, who was also a physician, and wealthy, obtained permission from the authorities to receive inebriates in his home for treatment on this plan. Three chronic cases were put under his charge, and were given brandy in all their food and drink, and not allowed to take any food that was not saturated with some form of alcohol. Each patient was given that kind of spirits which they had used commonly, in addition to the brandy. In the course of two months six patients were received and treated on this plan. One of them died two weeks after admission, of apoplexy or cerebral hemorrhage; two developed dangerous cases of delirium tremens, and were sent to the hospital; the fourth patient became violently delirious, and destructive in his mania, and was committed to an insane asylum; the other two seemed to have gone on quietly, in a condition of semi-stupor, or alcoholic narcotism. The authorities interfered, and the clergyman was forced to move away to escape persecution from the indignant friends of the patients. In a copy of the London *Times*, of 1860, I find a letter from a Dr. Brown, stating that he tried this plan of treatment for two days in three cases, and the effects were so alarming that he gave it up.

Another plan of treatment practiced by an irregular physician is claimed to be very successful, which is, to place the patient in a room and give him a large quantity of the kind of spirits which he has formerly used, and teach him to graduate the dose down to nothing, acting entirely on his free will and judgment.

The impression prevails that inebriety comes, in a large degree, from the use of adulterated spirits; also, that the real remedy would be pure forms of alcoholic drinks. A physician placed his son, an inebriate, under my care, advising me if the reaction from the withdrawal of alcohol was attended with any degree of exhaustion, to continue its use again, only securing the best and purest forms of liquors. This I declined to do, and the son was taken home; the father purchasing a large quantity of the best forms of brandy, attempted his cure at home by the means of pure spirits or liquors.

The dangerous properties of alcoholic drinks come from the different kinds of alcohols, depending on the processes of manufacture and the chemical changes which come from it, and not on the adulterations or presence of foreign substances which the retailer may combine. What is called the purest alcoholic drinks, such as old brandies and wines, are always the most dangerous, from the presence of those complex alcohols whose effects are as violent as they are uncertain. New wine is the purest and safest of all drinks that have any form of alcohol in them.

The advice, not unfrequently given to inebriates, to change the form of drink used, is attended with dangerous results always, for the probable reason that the use of new forms of alcohols may not only increase the degeneration produced by the former drinks, but excite new pathological changes in the nerve tissue more profound and fatal than before. A good example of this was that of an inebriate, of wealth, who had drank brandy and was considered a typical moderate drinker. He was advised by his physician to use whisky, as being less dangerous. He procured a choice article, of age, and so-called purity; and some months later he was taken to an asylum, a hopeless case of softening of the brain. I think it by no means improbable that the use of a new form of alcohol precipitated the final result. This has been noticed in beer drinkers, who after a certain stage begin to use the stronger alcohols and develop, shortly after, conditions of profound degeneration.

Another grave mistake is often made in advising patients to go abroad or travel, supposing that they can by this means more effectually break up the desire to drink. The irregularities of living, and the nervous strain consequent on travel, always more than counterbalances the advantages of change of scenery and surroundings. Travel in Europe is especially dangerous for all inebriates and opium takers. The opportunity for securing all forms of stimulants, and especially alcoholic drinks, is so great that it is almost impossible to get along and not use them. Many inebriates give up the stronger alcoholic drinks of this country when they go to Europe, and use wines, and as they rarely suffer toxic symptoms, are deluded with the hope of ultimate recovery, by the gradual reduction to less and

less dangerous spirits, until they are able to give up its use altogether. Invariably, on their return, they fall back on the stronger alcohols, and go down precipitately to more chronic conditions than before. The use of wine or beer in all cases of inebriety as a substitute for stronger drinks, is, in my experience, always attended with very bad results. In opium cases, travel to Europe for the purpose of breaking up the use of opium is almost invariably followed by the excessive use of alcohol. Wine and lighter drinks are found in a large degree to take the place of opium, and the latter is, after a time, given up. The transition from inebriety to opium eating, and *vice versa*, is very easy and rapid, and the diseased condition of the system may demand, any time, either one or the other. Experienced physicians are very careful in using opium as a remedy for inebriety, or prescribing any form of alcohol to opium takers. The use of chloral as a stimulant has often begun in inebriates, as a substitute for alcohol, and later, when such cases came under medical care, they are often regarded as *sui generis*, and their alcoholic origin overlooked.

All reliance upon certain specifics or special treatment will end in failure and disappointment. Efforts to find some class of foods which shall antagonize the disordered craving of the inebriate, will of necessity fail, because the complex diseased condition of which this is but a symptom cannot be reached by single remedies or forms of treatment.

An enthusiastic physician received two chronic cases into his family, some years ago, and treated them exclusively on the Graham system, with frequent hot water baths. Both cases recovered, but relapsed in a few months and became worse than ever. The physician had, in the meantime, published his experience as evidence of the value of this system of treatment, and he is even now quoted as having great success in this method, although he never treated any more cases.

The power of prayer and faith, urged by many clergymen, and used in some asylums as an exclusive method of treatment, has been followed by no satisfactory results, and, as an exclusive remedy, has no basis, in either science or religion. This teaching or theory, urged by Mr. Moody and his followers, has done much harm, by appealing almost entirely to the emotional nature of the patient, which sooner or later results in reaction and a greater degree of degeneracy than before.

The legal methods of treatment by punishment in jails is, in spirit and theory, identical with the efforts to suppress witches, and the persecution of the insane, by legal whippings and burnings.

The following case, which came under my care a few years ago, illustrates many points which have been presented, and indicates the true spirit upon which the treatment should be carried out:—

H., the only son of a prominent physician, came under my care for chronic inebriety, of five years' duration. He had evidently inherited an insane neurosis, and, from exposure in the army, became an inebriate. He drank constantly, was full of delusive plans and schemes for the future, seemed anxious to recover, but made no personal exertions to accomplish it. He was rarely intoxicated, but always under the influence of alcohol. Two years before coming under my care he had an attack of delirium, and was taken to Dr. Kirkbride's, in Philadelphia, where he remained six months, and came out in good health. A few months later he relapsed, and began to grow gradually worse up to the time of his admission at Walnut Hill. He was discharged three months later, at his father's request, that he might engage in business. He relapsed within a year, and, by the advice of a physician, went to Europe with an attendant, expecting a change of scenery and living would bring on restoration. He returned much worse, and was placed in the country, and the cinchona specific tried fully; this compound took the place of alcohol, but when abandoned, alcohol was resumed again. He was converted at this time, signed the pledge, and started out very confidently on a life of total abstinence. A few months after, all these hopes were abandoned, and he drank more impulsively than before. The next year was passed alternating between the seashore and mountains and various mineral springs, consulting both regulars and irregulars, using all forms of remedies and means to restore his health, without any results, except that he was steadily growing worse. The following extract of a letter to me, from his father, clearly indicates the principles of treatment which should apply in nearly all cases:—

"I have decided to trifle no more with H.; his disorder must be met by means adequate to reach it. I have had him legally committed as an inebriate, and shall send him to such an asylum and endeavor to keep him there until he recovers, even if it requires a lifetime to accomplish it. He has promised to remain one year in an asylum, and if he relapses after coming out, I shall send him back another year. I am convinced that the only hope for such cases is

in long continued residence in special asylums for this class, where medical care and restraint can be constantly applied. I do not mean that years of permanent residence in such places are essential, but I would return every case that relapses, for longer or shorter intervals, depending upon circumstances, extending through a long lifetime, if necessary."

All inebriate homes or asylums are nothing more than hospitals, where the patient can recover, and where all the means which science and experience indicate can be concentrated to make restoration more or less permanent. Failure to cure every case is no fault of the hospital, but usually from the want of the persistent use of the means necessary.

CASES OF WOUNDS OF THE CORNEA, WITH REMARKS ON THE USE OF SULPHATES OF ATROPIA AND DUBOISIA.

BY D. B. D. BEAVER, M.D.,
Of Reading, Pa.

The following cases of wounds of the cornea are presented as possessing some features that are peculiar, and of infrequent occurrence, and others that, although common, are often overlooked.

W. Y., aged eight years, was brought to me in October, 1879, with the statement that a week previously his right eye became sore, for which he was taken to an apothecary, to ascertain whether or not a foreign body was in it. The apothecary, after examining the eye, assured the mother that there was nothing in it, and that there was no need of consulting a physician, and, as is usually done, sold her a bottle of medicine.

Upon opening the eye I found pieces of five prickles of a chestnut burr in the cornea, of which four had pierced it entirely and presented their points in the anterior chamber, barely free from contact with the iris and lens. Three had gone through the cornea at right angles with its surface, near the centre, in the area of a moderately dilated pupil. The other struck the cornea at a more acute angle, in an outward and downward direction, about two and a half lines from the corneo-scleral junction, and extended into the anterior chamber, with its point just free from the iris. There was slight pericorneal congestion, with some photophobia and lachrymation, but not pain sufficient to disturb the child's rest at night, and no opacity or inflammation of the cornea, nor implication, in any way, of the iris. One of the less unfortunate features of the injury was, that none of the prickles broke above the surface of the cornea. If they had, the contact of the moving lid with the exposed ends would probably have moved them back and forth so much as to enlarge the apertures in the cornea, and thus allow the aqueous humor to exude and their points to puncture the capsule of the lens. This accident was the main danger in the case, and was to be guarded against in the abstraction of the foreign bodies. In order to do so, the first step taken was to make an incision, about one line long, over the prickle which pierced the cornea slantingly (of which the broken end was so far below the surface of the cornea that it could not be reached with a needle, without almost certain danger of opening the anterior chamber), in the direction of its length, and through more than half the depth of the corneal tissue, so as to lessen the resistance to the forward pressure of the point by the iris and lens during the loss of aqueous humor which would necessarily accompany the extraction of the others. Then, that one of the others, which extended furthest toward the lens, and almost touched the capsule, was picked out with the point of a Graefe cataract knife, and the others in the same way, in quick succession, before enough aqueous humor was lost to bring the lens in contact with any of them. During and after the extraction of these the aqueous humor discharged until the remaining (slanting) prickle was drawn flat against the membrane of Descemet, by the iris and lens, as was desired, without wounding either of them. After the anterior chamber was refilled the point of the prickle receded from the surface of the cornea, to about midway between it and the iris.

Believing that it could cause no harm there, that it would probably be drawn closer to the cornea again by the contraction of the inflammatory matter, which would form around it during the healing of the incision, and that consequently it would be more dangerous to extract so sharp-pointed a body than to leave it where it could not injure important structures, it was left there, and further results awaited. The vascular injection and other signs of irritation subsided in a few days, and the eye got well, with full vision, and has remained so to this time. The father of the child informed me, a week ago, that the prickle is still there, with its point drawn a little nearer to the cornea, as was expected, and that it appears to have lost somewhat in length, which is owing to the solvent action of the aqueous humor.

If a rupture of the capsule and opacity of the

lens, with considerable signs of intra-ocular irritation had been discovered, different operative interference would have been required.

It would then have been better to remove all the foreign bodies, even if it had been necessary to extract some through an incision in the cornea, because the swelling of the lens consequent upon the permeation of its substance by the aqueous humor would have pressed the iris forward against any remaining one, and thus aggravated existing irritation.

But as things were, the first consideration was to save the capsule and iris, and the best method of doing this was to remove as many prickles as possible with safety at once, and change the position or mobility of the remaining ones, so that they could effect no harm in the event of the loss of aqueous humor.

It did not seem probable that all could be taken out before the anterior chamber would be emptied, so the one which appeared most difficult to extract, and yet easiest to keep from injuring the parts behind, was allowed to remain.

This was the one that had pierced the cornea slantingly. It could, of course, also have been taken out, but not without opening the anterior chamber, either by an incision and the use of forceps, or with a needle introduced, and pressed against its point. The first method would not have been practicable until after the anterior chamber had become filled again subsequent to the extraction of the other prickles, when it would probably have been too late to prevent the injury the operation was intended to avert; and the latter would have been exceedingly difficult to execute, because the point of the foreign body was so close to the iris that it would almost certainly have been wounded with the needle, which would have given rise to hemorrhage, and interfere with the further progress of the operation. With these views the course here described was taken, with the intention of removing the remaining prickle if all irritation would not subside; but the result did not indicate any necessity of doing so.

It might be questioned whether a puncture of the capsule so small as would be made by a single prickle of a chestnut burr would endanger the lens. There are on record many cases in which larger ruptures of the capsule healed without leaving changes in the lens sufficient to impair vision, but they form the exception rather than the rule.

In the fall of 1877 I was consulted by D. H., æt. thirty-four, from a neighboring village, who, while out chestnuting ten days previously, had his right eye struck by a falling burr. The eye was painful, the pericorneal vessel intensely injected, the iris cloudy, and the pupillary edge adherent in points to the ruptured capsule, the lens swollen enormously, and tension increased.

This condition continued, in spite of medical treatment, and hence I deemed it best to extract the lens.

The result was good: $V = \frac{15}{20}$ with $+ \frac{1}{5}$. Upon close examination of the cornea with oblique illumination, only one very minute punctate scar could be detected on the cornea. Evidently, then, a single pin of the burr did all the mischief. In such cases, as in many other injuries of the eye, the importance of examining carefully the cornea cannot be overrated. The diagnosis and prognosis often turn upon the presence or absence of a scar on this part of the ball. This is well illustrated in the following case: Mr. H. came to me in February, 1879, saying that two days before, while he was driving a nail into the lid of a wooden box, he felt something going into his left eye. When I saw him he had no pain and the eye did not appear sore. Oblique illumination revealed a small linear scar, not over half a line in length, in the cornea, over the edge of the contracted pupil. The sight was somewhat impaired, but no wound could be seen in the iris nor the pupillary area of the capsule. Upon dilatation of the pupil with atropine, a rupture was discovered in the anterior capsule, a little higher up than in the cornea, and another in line with these, in the posterior capsule, from which a grayish white linear opacity was seen to extend upward and outward, until lost in general haziness, near the retina. The foreign body had evidently lodged somewhere near the retina, and would probably, sooner or later, cause disturbance. If it had gone directly through the posterior layers of the eyeball, there would, probably, not have been more diffuse cloudiness in the posterior than in the anterior portion of the vitreous, except in case of hemorrhage from a wounded retinal and choroidal vessel, because all the parts of the body are homogeneous. There was no effusion of blood from any of the vessels.

An unfavorable prognosis as to the ultimate result was given, notwithstanding the entire absence of all symptoms of irritation, and the patient advised to lose no time in seeing an eye surgeon, if pain or inflammation should appear in the eye.

Four months later his medical attendant informed me that the lens had been entirely ab-

sorbed, without any bad symptoms, but that the capsule had become opaque, and obstructed vision. Since then I have been informed that later another person performed a needle operation on the capsule, and that it was followed by soreness of the eye and atrophy of the ball.

In this case the foreign body struck the eye in an upward and outward direction, while the patient was looking down, with the head inclined and the brim of the hat shading the eye, which induced dilatation of the pupil to such a degree that the foreign body, probably a small piece of iron from the nail or hammer, passed through the lens without injuring the iris, so far from the centre that the wound was entirely covered by the iris when the patient presented himself. The small scar in the cornea could very easily have been overlooked in a cursory examination, but with the aid of oblique illumination, it was at once discovered and its depth observed.

This method of lighting up the anterior part of the eyeball is so simple and effective that every one who is called upon to treat injuries of the eye, can and should use it in every case in which a lesion becomes not at once apparent with unaided vision. It must have been the experience of every person who sees many cases of wounds of the eye, to have met frequently some in which no lesion or foreign body was visible until after a convergent stream of light was directed obliquely upon the cornea. It occurs most frequently in cases of injury by pointed instruments, pieces of gun cap, and specks of iron and emory.

Mydriatics, in the present fashion of using them for all sorts of pain in the eyes, are often applied very improperly in wounds of the cornea. This is well shown in this case: W. F., aged three years, was sitting on the front door-step while some one was cleansing the glass in the window directly overhead. The noise attracted his attention, and while he was looking up a pane was accidentally broken, and a piece of it in falling struck him in the right eye. When he was brought to me, ten days later, there was a linear cicatrix, one and a half lines long, in the inner lower quadrant of the cornea, extending from the sclero-corneal junction, upward and outward, to which the pupillary edge of the iris was attached by inflammatory matter. The irritation which followed the injury had disappeared, and the wound was healed; but the pupil was very much displaced toward the scar, causing an unsightly deformity. And, in consequence of the peripheral position of the pupil, vision was somewhat impaired. The pupil was partially dilated by a solution of atropia, which the attending physician had ordered. Here a grave error was committed in dilating the pupil. The result of it was a deformity and loss of vision, which could be remedied only by an operation upon the iris. A directly opposite method should have been employed. Eserine should have been instilled, and the pupil kept in a state of contraction until the corneal wound was healed. If the part of the iris opposite the wound had then become adherent, the natural position and shape of the pupil would yet have been preserved. If there had been a protrusion of a portion of the iris through the wound, which would have resisted the action of the constricting fibres under the influence of eserine, a gentle effort should have been made to reduce it with a blunt instrument, and this failing, it should have been abscised.

On the other hand, we meet frequently cases of perforating wounds of the central part of the cornea, in which the first effort of the attendant should be directed toward dilatation of the pupil, and yet, in which he has entirely failed, although there may not have been iritis or intense inflammation of any part of the eye. In most cases this is owing to the use of too weak solutions of mydriatic medicine. If atropine be the remedy, a solution of not less than four grains to the ounce should be used, to obtain dilatation, which, when once produced, can generally be maintained by weaker ones, unless severe iritis supervenes. In that event stronger ones, six to eight grains to the ounce, will be equally uncertain, unless supplemented by mercury to the extent of touching the gums, and leeches or cups to the temple. In quite young children, and in adults who are peculiarly susceptible to the influence of belladonna, the instillation of the four-grain solution is sometimes followed by the general physiological effects of the drug. In the case of children under two years, it is well to make pressure upon the lachrymal sac with the end of the fore-finger, covered with a fold of a linen handkerchief, while the medicine is being dropped into the eye, to prevent the passage of the whole quantity into the nose and throat; or keep the patient under observation until after its full effect upon the pupil is produced, especially in cases in which there is not much inflammation and lachrymation. Under such circumstances there is more absorbed by the conjunctiva, and more finds its way to the throat, than when there is conjunctivitis and the tears flow freely immediately on opening the eye.

Duboisia is commonly used in about half the dose of atropia—that is, a solution of two grains

to the ounce of the former is used for the same purposes as a solution of four grains to the ounce of the latter. This practice seems, however, to be based upon the similarity of the general effects of these two solutions, rather than upon their action on the pupil and ciliary muscles, the object of their use being always to impress the accommodative apparatus of the eye as much as possible, without producing discomfort in other parts of the body. They are both about as strong as can be used without causing, frequently, dryness of the throat, giddiness and flushed face; and in my experience, one has produced these effects about as often as the other. It is probable that the full mydriatic effect of either medicine could be exhibited by the use of weaker solutions in eyes free from inflammatory disease, and that their true relative power to paralyze the ciliary muscle through local application could be better determined thereby.

I have not made any precise experiments regarding this point, but frequent use, in practice, of both articles, in weak solution, one-fourth to one grain to the ounce, leads me to believe that the mydriatic properties, as Ringer and others have found the general effects of duboisia, are very much more than double those of atropia. That it possesses any advantage over atropia, in the treatment of diseases and injuries of the eye, remains yet to be proved. I have used it during the last year and a half about as often as atropia, without finding any difference in its favor, except in several cases in which atropia seemed to aggravate the existing irritation. In one of these its beneficial influence was very marked.

W. K., aged fifty-five years, came to me with a small round ulcer near the centre of the left cornea, which had been treated six weeks with atropine drops, by his physician, under the advice of a specialist, without improvement.

The ulcer was about one line in diameter, excavated, with regular edges, nearly clean base, and surrounded by a narrow opaque zone, which shaded off gradually into the healthy cornea. There were a few blood vessels running to it from the periphery of the cornea, which indicated a tendency to separate action. The conjunctival and pericorneal radiating vessels were intensely injected, and there was lachrymation, a high degree of photophobia, and pain that had disturbed his sleep during the last week. Tension was normal. The disproportion between these severe symptoms and the appearance of the cornea was so prominent a feature of the case as to lead to suspicion that the long continued use of atropine was prolonging and aggravating the disease. The atropine was discontinued and one drop of a two-grain solution of duboisia sulphate instilled every four hours, and one-fourth grain of morphia ordered to be taken often enough to relieve pain and induce sleep. Improvement began at once and progressed so rapidly that on the fourth day the patient was sent home, with instructions to return upon the appearance of any unfavorable change. At the end of a week he returned with the eye free from pain and congestion, and a small opacity occupying the site of the ulcer. A mercurial salve now completed the cure.

REPORT OF A CASE OF TUBERCULAR MENINGITIS.

BY D. A. HENGST, M.D.,
Of Pittsburgh, Pa.

The following case is reported, not on account of any unusual symptoms presented, but on account of its rapid course and the age of the patient, the disease being extremely rare during the first year of life. I was called September 17th, 1880, to see Alice B., æt. nine months; the child's mother stated that she had been vomiting since the 13th, four days ago. She had always been bright and healthy up to within three weeks ago, when she had a severe attack of diarrhœa, lasting about one week.

The child looks pale and emaciated, eyes sunken but pupils natural, tongue coated, temperature normal, pulse one hundred and twenty. Upon examination of gum, find that it is hard and swollen over the left upper incisor tooth.

The family history is good, with this exception: its mother informs me that her mother died of phthisis.

I cut the gum, and ordered one-eighth grain of calomel to be given every hour until vomiting stops.

September 18th: vomiting has ceased, but patient not any better in other respects; is very dull; does not notice anything; respiration sighing and very irregular; pulse one hundred and eighty, temperature 102°; head thrown back; face pale at times, and at others it is flushed; bowels moved several times since yesterday, but discharges natural in appearence. I ordered for it the following:—

℞. Potass. citrat., gr. ij
Mist. neutral, ℥ j. M.

Sig.—To be given every three hours: also to apply a mustard plaster to the back of its neck every two hours.

September 19th. Very little change in her

condition since yesterday. Continues very dull; wakes with a sudden cry at intervals of half an hour; retraction of the head continues; pulse 140, temperature 101°; respiration irregular and about ten per minute; pupils natural but very sensitive to light. Child will not nurse; directed that it be given one teaspoonful of beef tea every hour.

September 20th. Not so well; more comatose than yesterday; pulse 130, temperature 102; sighing respiration; pupils slightly contracted, the right smaller than the left; bowels not moved for two days; retraction of the abdomen. Tendency to convulsions of an epileptiform nature; the forearm of the left side contracted upon the arm and the thumb flexed within the hand, the left leg partly flexed upon the thigh; there is also a great deal of muscular twitching. There is no cough and the respiratory sounds are normal.

I ordered one teaspoonful of castor oil, to move bowels, also the following:—

℞.	Potass. bromid,	gr. ʒ i–ss	
	Spts. nit. dulc.,	ʒ j	
	Tr. belladon.,	gtt. viij	
	Syr. simp.,	ʒ ss	
	Aquæ menth., ad	ʒ j.	M.

Sig.—One teaspoonful every three hours; and directed that the child be put in a warm mustard bath every two hours.

September 21st. Not improved; pupils irregular; morbid strabismus; flexion of both thumbs into hands; muscular twitching continues; more comatose; respiration sighing and about ten per minute; pulse 140 and irregular; temperature 102½°; tongue coated with a whitish coating, and abdomen still retracted.

The oil moved bowels freely. Now I ordered the following:—

℞.	Quinia sulph.,	gr. viij	
	Ammoniæ carb.,	gr. vj	
	Syr. acacia,	ʒ ij	
	Aquæ menth. ad	ʒ j.	M.

Sig.—One teaspoonful every two hours; also twenty drops of spirits frumenti every hour.

September 22d. Has been very restless all night; more unconscious than yesterday. Pulse one hundred and fifty, fluttering and very irregular; respiration nothing but a drawn sigh every now and then; temperature 104°; pupils contracted but irregular, firm strabismus; epileptiform spasms more than any time before. Death occurred at two o'clock this afternoon.

Post-mortem examination made some hours after death, assisted by Drs. March and McNeil. Found about four ounces of fluid within the dura mater and upon the substance of the brain. The pia mater over left middle lobe of the brain highly congested, and slightly so wherever examined. At base of the brain the same membrane was found greatly thickened, and infiltrated with miliary tubercle, having a peculiar sand-like feel and appearance. The medulla and pons presented nothing abnormal, the substance of the brain being congested throughout its entire extent.

Medical Societies.

MEDICAL AND SURGICAL SOCIETY OF BALTIMORE.

Paralysis Agitans.

Dr. Caldwell. A man, aged fifty-five, suffered in an extreme degree with this disease. Potass. bromide, electricity, etc., were used without benefit. I gave him tinct. nuc. vomicæ, gtt. x. four times a day, gradually increasing until nearly a drachm was given at each dose. After using for about eight weeks he had a very violent seizure, showing the symptoms of strychnia poisoning. I feared a fatal issue, but by the free use of chloroform the convulsion was controlled, and the man has been free from his old malady ever since.

Dr. Rennolds. I treated a case of spermatorrhœa with strychnia. I gave him one-fortieth of a grain, thrice daily, gradually increasing until the daily dose was over one grain. It was continued in this quantity for over one week. The man improved rapidly, but no symptoms of poisoning appeared.

Membranous Croup.

Dr. Taylor. Some weeks ago, a gentleman in this society recommended iodide of potassium in large doses. Shortly after I was called to a case, and immediately put it upon fifteen grains, every two hours, and the child got well. Since then I have had several cases in which I used it, and all recovered. In one case tracheotomy was performed, with recovery. One of the patients expectorated a large quantity of false membrane.

Diphtheria.

Dr. Percivall. Some years ago an epidemic of diphtheria occurred in the town where I lived. The first case died before I saw it. Fourteen days after another child was attacked; sulphate of copper was used locally, but as it did not seem to answer the purpose, nitrate of silver (ʒ j–aq. ʒ j) was used instead. As prophylactics, the best of food and brandy were used freely. I had fifteen cases, and not one of them died. This disease is most prevalent among the poor, and I believe its great mortality is largely due to improper and insufficient food, and that if stimulants and tonics were used as prophylactics, a large number of the cases would be rendered more mild, if not prevented entirely.

Dr. Erich. Prophylaxis may be of some use, but I doubt whether we can do much with it. Since I read Oertel in Ziemssen's Cyclopædia, I have been a believer in the parasitic origin of this disease, and what I have seen since confirms

his statements. I have ceased to dread diphtheria since I adopted my present mode of treatment. Formerly I used nitrate of silver, but the struggling of the child seemed to do as much harm as the application did good. I think it highly important to use the medicine frequently. I use—

℞.	Quiniæ sulph.,	gr. viij	
	Tinct. ferri chlor.,	℥j	
	Syr. simp.,	℥iv.	M.

Sig.—Teaspoonful every hour, day and night.

Since I have adopted this method the results have been astonishing. I have used it four years and have only lost three cases. When I see the disease in an advanced stage, I alternate this mixture with a solution of benzoic acid, which seems to relieve the constitutional symptoms.

Dr. Arnold. The treatment of diphtheria is the opprobrium of medicine. Age has much to do with the prognosis; under two years it is an extremely fatal disease. Those cases associated with croup always die. If the patient be over two years and no formidable complications appear, any form of treatment may show good results. Different epidemics also show different rates of mortality. The profession is divided as to its pathology, but the paralysis of the pharynx, heart, etc., show that it is more than a local disease, at least in its secondary effects. The treatment mentioned by Dr. Erich is rational, though not novel, but I would not be too sanguine as to it curing bad cases.

Dr. Morris. During the last two years I have used no iron, quinine nor local applications in this disease. I use ice, food, and lemon juice freely, and have had better success than formerly.

Hydatiform Mole.

Dr. Opie. On December 26th I was called to see a lady with the following history: Was confined January 12th, 1880; menstruated April 30th; missed menstruation October 30th; had a flow begin November 14th, which continued until I saw her. On December 27th I found her bleeding quite profusely, and on examining some of the clots I found hydatiform cysts of the chorion. The uterus was as large as at the sixth month, and the os sufficiently dilated to admit the index finger. I removed the mass gradually so as to allow the uterus to contract as it does in natural labor. There was not much loss of blood, but little pain, and firm uterine contractions followed.

Aortic and Mitral Regurgitation.

Dr. Chambers. A colored boy, who had had rheumatism, complained of pain over the cardiac region. The pulse was weak, and upon examination aortic and mitral regurgitation was diagnosed, for which iron and tincture digitalis were prescribed, with the effect of making him worse. Digitalis was then combined with aconite, without benefit, and finally aconite alone was used, with marked improvement. It is a question whether digitalis might not do harm in aortic regurgitation, lengthening the period of rest, and thus cause greater distention of the ventricle.

Dr. Lynch. Digitalis is less useful in aortic regurgitation than in any other form of valvular disease. In mitral regurgitation it is our best remedy. There are two periods in cardiac trouble in which it is useful: in the beginning, before ventricular hypertrophy takes place, and in a later stage, when there is dilatation and debility of the ventricle.

Cancer of Stomach.

Dr. Brinton. I bring this man before you to get an opinion as to the diagnosis, my own belief being that it is a cancer of the stomach. He is fifty-seven years old, miller, but for the past two years has been working on mill-stones. Two years ago last autumn had stomach trouble, vomiting, flatulence, etc. Now he has attacks of pain to the left of the ensiform cartilage, lasting for two or three days, followed by vomiting of a dark, grumous matter, which gives relief, and then a repetition of the attack after a rest of one or two days. The bowels are open, without medicine, about every seventy-two hours. His weight has decreased from 147 to 121 pounds. His present attack has lasted two weeks. Solid food gives more pain than liquid, and cold water is not taken, on account of producing pain. There is no family history of cancer. The treatment has been dietetic, lime water and milk, and ten grains of lactopeptine and twenty grains of bismuth, four times daily.

Dr. Opie. I had a case very much like this about six months ago. I was of the opinion that it was cancer of the pylorus, but he passed from my notice and I do not know whether there was a post-mortem examination. I found that by restricting him to liquid diet and using one grain of carbolic acid and half a drachm glycerine, pro re nata, the vomiting was much controlled.

Dr. Cathell. In a case of mine, I met much the same symptoms. The post-mortem showed a strictured condition of the pylorus and seven inches of the small intestine. The orifice was not larger than a crow quill.

Dr. Chambers. The length of time this patient has been suffering in this way is against the belief that it is cancer. Two and a half years is a long time for a case of cancer of the stomach to last. This man has been a drinking man and may have had gastritis in the first instance. I should use nourishing enemata, as milk, blood, etc., and give the stomach rest. For the pain, morphia, dry on the tongue or hypodermically, would be the best remedy.

Diphtheria in Russia.

The United States Consul at Moscow sends a report of Dr. Bulewsky concerning an epidemic of diphtheria at Samara, a city on the Volga river, about 900 miles from Moscow. Children attacked under one year of age, not fed from the mother, died, almost without exception, while sucklings generally recovered. Of those between 1 and 5 years 86 per cent. died. From 5 to 10 years the mortality was 80 per cent. of the cases. The cases among males and females under five years were about equal, but between 5 and 20 years, more than twice as many females as males were attacked, owing to the confinement of the former in infected houses, and their duties as nurses, while the males were at work in the fields.

Editorial Department.

Periscope.

Two Cases of Disease of the Pancreas.

Affections of the pancreas are very rare. Grisolle, during thirty-five years of practice in the Paris hospitals, did not observe a single case of pancreatitis. M. Dethier, Physician to the Civil Hospital at Namur, reports two cases in the *Journal des Sci. Med. de Louvain*, Dec. 1880.

The first was a case of chronic pancreatitis, terminating in suppuration. A woman, sixty-six years of age, became very feeble, and lost flesh rapidly; there was intense jaundice, the urine containing large proportions of the coloring matter of the bile, the fæces were clay-colored. Digestion was difficult, vomiting of aliment occurring from time to time. The liver was enlarged and hard, with no irregularities on its surface; painful on pressure. There existed evidently some obstruction to the passage of bile; as the patient had never suffered from colic, this evidently was not due to the presence of a calculus. By careful palpation, a tumor was discovered, situated deeply in the epigastric region: it extended transversely in the place occupied by the pancreas, and was painful under pressure. M. Dethier was of the opinion that there existed inflammatory disease of the pancreas, the head of this organ, by its increase in size, causing obstruction at the orifice of the common bile duct in the duodenum. The patient died four months later, in a state of marasmus. At the autopsy the liver and gall-bladder were found gorged with bile; the thumb could be passed into the enlarged ductus hepaticus, while its orifice in the duodenum was impermeable. The right half of the pancreas was enlarged, red, and hard, and the head being incised, a cavity, containing a spoonful of pus, was found.

The second case was one of primary cancer of the pancreas. The patient, a clerk, thirty-five years of age, had never had jaundice, but for five years he had been subject to attacks of gastralgia. He lost flesh; his skin took on an unhealthy, pale-yellowish tinge; he never vomited, and was rather constipated until shortly before his death. By careful palpation of the abdomen, a small, deeply-seated tumor was found in the epigastric region; it gradually enlarged and invaded all the right half of the abdomen, and became nodular and irregular on the surface. As there was no vomiting, M. Dethier was of the opinion that the tumor had its seat in the pancreas, and the correctness of his supposition was proven at the autopsy. On opening the abdomen a large, white tumor, of scirrhous nature, came into view; it extended from the liver to the vertebral column, involving in its mass the pylorus and the upper part of the duodenum, the common bile duct remaining free. By dissection it was found that the tumor had invaded almost the entire pancreas, the pylorus was transformed into a rigid, dilated canal, into which three fingers could be passed, thus explaining the profuse diarrhœa, a veritable lientery, which came on shortly before death.

Mental Failure, from Strain.

The *Medical Press and Circular* states that Dr. Maclaren, superintendent of a prominent insane asylum, has observed among the patients sent to that asylum a form of insanity which is not melancholia, and which is not dementia, although it may, at first sight, be taken for one or other of these, but which seems to be grave nervous exhaustion. It persistently appears in men who belong to the skilled artisan class. It must be remembered that the intelligent workman of the present day is a very different person from the laborer of a former one, and uses, and probably overtaxes, his brain nearly as much as professional or business men do. The attack to which Dr. Maclaren refers especially affects the middle-aged, whose previous history is that they have been steady, hard-working men, who have saved a little money and who have always been of an anxious turn of mind. In almost all instances they have been men of aspiring temperament, but without the intellectual ability which has enabled a few of their class to rise entirely above it. Yet they are not content to remain in their station, and so they plod and toil, and become a prey to anxieties. Ultimately the prospect of attaining a high position is lost, and then they concentrate their desires on accumulating money. Their whole time is occupied in laboring and planning to increase their store, and they are vexed by apprehensions lest their schemes should miscarry. The hours which should be devoted to sleep are given up to work, or miserly calculations, and then when an illness or a grief comes upon them they break down miserably. They are reduced to a state of utter and complete prostration, mental and physical. The surface of the body is cold and pale, the pulse is feeble, and the mental condition is listless to an extraordinary degree. Power and force seem gone forever, and the stalwart, well set up, acute looking artisan of a short time ago is reduced to a gray, bent, nerveless invalid. In this utter loss of physical power is one of the marked distinctions between this variety of mental disease and melancholia. The cases of this kind which Dr. Maclaren has seen improved under treatment, but never recovered the tone of former days.

Stretching the Facial Nerve for the Relief of Spasm of the Facial Muscles.

At a meeting in November, of the Clinical Society of London, Dr. Allen Sturge and Mr. Godlee presented a paper on this subject. The patient, a lady, æt. seventy two, had been sent to Dr. Sturge by Mrs. Garrett Anderson. She had enjoyed good health until the death of her husband, six years ago. After this her nervous system suffered much; she had fits of depression

and debility, and before long twitching began round the right eye, extending subsequently to all the muscles supplied by the right facial nerve. She had gone through various courses of treatment without result, and she finally consented to have the facial nerve stretched. This operation was performed by Mr. Godlee on July 20th, by means of an incision behind the ear, from the external meatus nearly to the angle of the jaw. The sterno-mastoid and the parotid gland were pulled in opposite directions, exposing the upper border of the digastric close to which the nerve was found, as it emerged from the stylo-mastoid foramen. The nerve was raised on a hook and pulled with moderate force. After a few such pulls the right side of the face was completely paralyzed. The wound was dressed antiseptically, and healed without a drop of pus, or the slightest constitutional disturbance. The face remained paralyzed for two months, and for some days after the operation there was a good deal of pain on the right side, and also in different parts of the head, which returned at intervals during these two months. When seen on October 19th. three months after the operation, the face at rest was nearly symmetrical on the two sides, but there was still a good deal of deficiency of movement in the muscles on the right side. She was, however, rapidly improving, every week making a considerable difference. The operation has now been performed five times, three times in Germany by Baum, Schussler and Eulenberg, once in America by Dr. James J. Putnam, the present case being the first operation of the kind in England. In all these cases there was temporary paralysis after the operation, varying from two weeks in Baum's case to five months in Eulenberg's. It was remarkable that in every case in which the facial nerve had been stretched for spasmodic tic the operation had been successful, while in several cases of spasmodic affection of other parts, as of the arm, etc., stretching the nerves of the part had produced no good effect.

Prof. Esmarch's Antiseptic Methods.

Mr. Little, a London surgeon, who lately visited Esmarch's hospital, at Kiel, contributes to the *Medical Press and Circular*, December 1st, a description of what he saw there. We make the following extract, as of general interest, and as an appendix to what we quoted last week:—

The most noticeable feature is the success achieved by Professor Esmarch under the system of infrequent antiseptic dressing, it being a by no means uncommon event for the first application to be left undisturbed for a month, and thus one of the objections to the antiseptic method, viz., its expense, is removed. In all cases the temperature is carefully watched, and the exterior of the dressings examined daily. On the slightest sign of discharge soaking through, or serious rise of temperature, the dressing is removed and reapplied.

The temperature of the patients, is, as a rule, taken in the rectum, and hence some deduction must be made in comparing the cases with those in which it is taken in the axilla.

The antiseptic method of Lister, or a modification of it, is, wherever practicable, employed. In place of antiseptic gauze, large pads of carbolized jute (enclosed in antiseptic gauze), or of carbolized hydrophil cotton, which readily absorbs discharges, are used, with carbolized varnished paper over all, and starched gauze bandages; protective is not used. The bone drainage tubes invented by Prof. Esmarch's senior assistant, Dr. Neuber, are extensively used; and, indeed, without some such self-removing drain, the dressings could not, in resection and other cases, be left untouched for so long a time as they are left with its help. The tube is kept in its place by being simply transfixed at its outer end with a common safety pin; and when, after two or three weeks, the first dressings are removed, these pins are usually all that remains to show where the decalcified bone tube has been. The tubes, as used here, are quite soft and flexible, not brittle.

The solution of carbolic acid used for the spray is of the strength of one in forty, and it is not thought necessary to have the sprays playing immediately on the wound, but this latter is thoroughly and often washed out with carbolic acid lotion; and in the operating theatre, which is exceptionally well fitted up, two powerful sprays, worked by compressed air, conducted in pipes from the engine-house, are kept going, throwing the pulverized carbolic acid solution over the table and above the heads of the operators.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——"The Philosophy of Restoratives," is the subject of a reprint from the American Medical Association Transactions, by Dr. John R. Uhler, of Baltimore.

——In a reprint, Dr. N. H. Chapman, of this city, records a case of extensive scalding from prolonged exposure to steam at a high temperature. In spite of the large area of the lesion, the patient recovered.

——The various eruptions produced by medicinal agents have been studied in a thorough manner by Dr. Arthur Van Harlingen, of this city. His results are embraced in a reprint from the *Archives of Dermatology*.

——"Sclerotomy in Glaucoma," is the subject of an article in one of the German journals, a reprint of which we acknowledge from the author, Dr. M. Landesberg, of this city. It will be found a succinct exposition of the question.

——The *Popular Science Monthly* is always welcome, but the February issue is especially at

tractive. It always contains articles of moment to physicians, and it will be found an admirable repertoire of the latest discoveries in modern science and exploration.

——*Godey's Lady's Book* for February is well filled with matters of interest to ladies. Each number now contains a complete novel, at the same time that all the old departments are retained. The price is only $2.00. Published at 1006 Chestnut street, Philadelphia.

——Brooklyn has still another medical journal, *The Pathologist*, monthly, $1.00 a year. Vol. I, No. 1, has 12 pages. No editor is named. Several of the articles are well written, and the editorial is a very determined declaration of independence from the medical control of New York city.

——The *Annals of Anatomy and Surgery*, published in Brooklyn, is a continuation of the *Annals of the Anatomical and Surgical Society*. The present editors are Drs. L. S. Pilcher and Geo. R. Fowler. They intend to extend the scope of the journal, and improve it in various ways. We have, on previous occasions, expressed our high esteem for this publication.

——Numbers IV, V and VI of the "Photographic Illustrations of Cutaneous Syphilis," by Dr. George Henry Fox, have appeared (Published by E. B. Treat, No. 757 Broadway, N. Y. Price per number, $2.00). We can continue to refer to them in the highest terms, as admirable illustrations of the disease in question; better than anything that the art of the engraver can furnish, inasmuch as they are absolutely faithful to Nature herself. The particular lesions represented in these numbers include papular and pustular syphilides, onychia syphilitica, pemphigus iris, eczema squamosum, and ulcerative tubercle. The text contains descriptions of the photographs and also a well prepared chapter on the classification of the syphilodermata.

——Those who have to treat cases of consumption might derive benefit from the perusal of a pamphlet on Phthisis Pulmonalis, and its Treatment with Hypophosphites, by Dr. L. De Bremon, late clinical assistant to Dr. Churchill. (John Newton, Publisher, New York city.) He makes some useful points, as this one:—

"A suggestion that I would offer to my professional brethren is that the doses that are recommended for general use are too large, and sometimes enormous, surpassing three times the doses that Churchill has given as a general limit to obtain good therapeutic effects.

"My own experience of more than twenty years in the treatment of the disease corresponds entirely with his directions.

"It is true that at the beginning large doses will work marvels, but it will soon be shown that they aggravate in place of curing, and in the end will do more harm than good."

——A report on vaccination, to the South Carolina Board of Health, by Dr. S. Baruch, of Camden, S. C., contains much interesting matter, and especially points out the decreasing power of vaccination as a prophylactic. He writes:—

"In the epidemic prevailing in Switzerland from 1825 to 1829, only two per cent. of the deaths were among the vaccinated; in France only one per cent., and that the average per cent. of deaths among the vaccinated in all the epidemics alluded to, up to 1859, is 4.32 per cent., while the average per cent. of deaths among the vaccinated in the epidemics of later years is 12.52 per cent. This difference is so great in favor of the earlier vaccinators that ample allowance can be made for possible errors, and still leave us no alternative but imperfect vaccination to explain the increased mortality among the vaccinated in the last ten years."

Probably the older humanized vaccine matter had lost its effects. The true remedy lies in the general use of bovine lymph.

BOOK NOTICES.

Hernia, Strangulated and Reducible. With Cure by Subcutaneous Injections. Together with Suggested and Improved Methods for Kelotomy. Also, an Appendix, giving a short account of various New Surgical Instruments. By Joseph H. Warren, M.D., etc. Boston: C. N. Thomas, 1881. Cloth, 8vo., pp. 280. Price $3.00.

From various articles which have appeared in this and other journals, the medical public is pretty generally aware that the operation for hernia practiced by Dr. Warren is a modification of that of Dr. Heaton, and described in a work written some years ago by this surgeon. It is not to him, however, that Dr. Warren gives the credit of its discovery, but to Dr. Joseph Pancoast, of Philadelphia. It is true that the latter never brought the method to practical perfection, nor did he carry out the line of investigation which he commenced; therefore he must divide the credit of the discovery with Drs. Heaton and Warren. The latter has made many improvements in the forms of the instruments used, in the details of the procedure, and in the after treatment. These are fully described in the volume before us, and it is recommended to all

who wish to study up this apparently highly satisfactory method for the radical cure of a large class of herniæ.

We regret to have to add that Dr. Warren's book is very indifferently published. The illustrations are wretchedly printed, the type blurred, and the presswork singularly careless.

Revelations of a Boston Physician. By Charles Wistar Stevens, M.D. Boston: A. Williams & Co. pp. 253.

The title of this little volume is hardly fair to its contents. The word "revelations" leads us to expect some indiscreet communications, some introductions to the coulisses and bed room business of the modern Athens. Nothing of the kind. We are treated to a number of little stories, generally pleasant and all harmless, incidents in the actual life of a physician of the poor in a large city. They are agreeably narrated, and are concerned with such subjects as "A Case of Poisoning," "Swallowing a Frog," "The Rag Picker's Death," "What my First Patient Cost me," etc.

Hand-book of Urinary Analysis; Chemical and Microscopical. For the use of Physicians, Medical Students, and Clinical Assistants. By Frank M. Deems, M.D. New York: Industrial Publication Co. 12mo., limp cloth. Price 25 cents.

This manual presents a plan for the systematic examination of liquid urine, urinary deposits, and calculi. It is compiled with the intention of supplying a concise guide, which, from its small compass and tabulated arrangement, renders it well adapted for use. It is a manual which will serve to lessen the difficulties in the way of the beginner, and save valuable time to the busy practitioner. The arrangement of the matter, and the small though clear type in which it is printed, has enabled the author to compress a great deal into a very small compass.

Elements of Practical Medicine. By Alfred H. Carter, M.D. Lond., etc. Philadelphia: Presley Blakiston, 1881. 1 vol., 8vo. Cloth, pp. 374. Price $3.00.

Dr. Carter is favorably known as a London physician of learning and experience, and a clear writer. His present volume is not at all an ambitious one. He states his object to be to provide the student with a general introduction to the study of medicine, and to bring its essentials within the grasp of those who are not disposed to read large and complete works. In other words, he aims to give a judicious epitome of practical medicine.

After an introductory chapter on general pathology, he takes up the various diseases, pretty much in the order laid down by the nosology of the London College of Physicians, giving in turn the causes, morbid anatomy, symptoms and treatment of each. The extent of the work may be judged from the space occupied by a few prominent diseases. Pericarditis covers two pages, pleurisy four pages, Bright's disease six pages, and measles one and a-half pages.

The work of condensation appears to be judiciously done, and as much is inserted as the restricted space permits. Of its kind, and for its purpose, it is a well prepared book.

Wood's Library of Standard Medical Authors.

Minor Surgical Gynæcology. By Paul F. Mundé, M.D.

A Treatise on Albuminuria. By W. Howship Dickerson, M.D. Second edition.

The energy displayed by Messrs. William Wood & Co., in publishing standard medical works in serial form, is highly to be commended, and we believe is appreciated and rewarded by an extensive patronage from the profession. Some of the works they have chosen for this purpose have been criticised, and we think justly, as representing a period of medical science which belongs to the past rather than to the present, and is of interest historically rather than practically. But this would not hold good of the two works which are mentioned above. They are both by active workers in the profession, and describe the portions of the field they are intended to survey, thoroughly and ably. Dr. Mundé always studies a subject exhaustively; some might say that his book might profitably have been reduced, as a good many of the instruments he describes are tentative and imperfect. But to many this is a praiseworthy fault, if one at all.

An Elementary Treatise on Practical and Analytical Chemistry and Qualitative Inorganic Analysis. By Frank Clowes, D. Sc. With Illustrations. From the Third English Edition. Philadelphia: H. C. Lea's Son. 8vo, pp. 372.

The intention of the author of this work is to furnish a course of instruction in practical chemistry in the laboratories of public and medical schools. It is extremely compact, the text clear, and a system of exhibition by tables adopted, which renders the differences manifest to the eye. Many will find this work sufficient for the chemical knowledge needed in medicine. The present edition has been thoroughly revised and is presented in clear type and on good paper.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA

THE ALLEGED HIGHER RATE OF MORTALITY IN THE MEDICAL PROFESSION.

A number of recently constructed mortality tables, showing the average length of life in different trades and professions, unite in seeming to indicate a gloomy prospect to physicians. For instance:—

Hecker confirms by his statistics a fact, indeed already known, that the duration of life among medical men is notably less than the mean. From Escherich's statistics it results that, in Bavaria, of one hundred individuals, fifty three Protestant pastors, forty-one professors, thirty-nine advocates or magistrates, thirty-four Catholic priests, and only twenty-six doctors, reach the age of fifty.

Kayser, writing from Breslau, finds in that region the average age at which the physicians die is at fifty-six years, priests fifty-eight years, professors fifty-nine years, higher office holders sixty-four years, apothecaries sixty-four years, lawyers sixty-four years.

There is, however, an element in these calculations to which considerable weight must be given, and that is the large number of men who leave the profession of medicine in early life to seek a living in some other vocation. If out of one thousand graduates, five hundred seek other employments, and of the remaining five hundred only one-half reach fifty years, it is obviously incorrect to say that out of a thousand duly graduated physicians only twenty-five per cent. reach the age of fifty years. Yet this is the error which it seems to us Escherich has committed.

It may be that a similar error vitiates Kayser's figures. In comparing physicians with the higher office holders, for example, we must remember that physicians begin their professional life early, holders of important offices late in life. Suppose that there are no high office holders under thirty years, while one-fourth of the physicians are below that age; evidently this would greatly reduce the average duration of life of the latter as compared with the former, even if after thirty the chances were the same. The average age at which people die after fifty is, of course, higher than the average mortality at all ages; but, for all that, their probability of life is materially diminished, and is much less than the average probability. In London, the average age of public house keepers is quite advanced; but their average mortality is high; apparently conflicting facts, which are explained by remembering that in that city public houses are usually kept by domestics, who retire from service at an already late period of life and open a bar with their savings.

Much depends on whether a business is such that an elderly man is prompted to retire from it early. Our army, in time of peace, has a very low death rate; but the average age at which the soldiers die is very low, something like 33 years, we believe. This is simply owing to the fact that the great mass of the soldiers are young men, and when their period of enlistment terminates, they leave the army and are replaced by still younger men. The disturbed hours, long drives, and irregular meals inseparable to a physician's life lead many to lay it aside for retirement or

other occupations when they reach that age at which these infractions of comfort become exceedingly onerous.

It is clear, from the above, that neither the average age at death nor the percentage remaining alive at a given age will alone acquaint us with the risk to life of any trade or profession. Not even when the average age of those living is taken into account, will either of them do so, because this average age depends upon accidental causes. In Kayser's tables the average age of the living lawyers is the lowest of eight professions; while their average age at death after 30 years is the highest; which he explains by the great number of mere students of law who were included.

The problem is a more complicated arithmetical one than is usually supposed. Its factors are 1. The total number of graduates. 2. The number who leave the profession, and at what age. 3. The average age of those remaining in the profession. 4. The average age at which the latter die.

These factors obtained and reduced by the rules of compound proportion, we should get at the truth about the alleged higher mortality of the medical profession, which, we believe, has never yet been correctly stated.

THE VARIATIONS IN PHARMACEUTICAL PREPARATIONS.

The position which should be occupied by non-officinal drugs and preparations, with reference to a fixed standard of strength, is one of the problems which confront both physicians and druggists. When they are not in the Pharmacopœia, every manufacturer makes them of the strength—or weakness—best suited to his own interests; and as the physician cannot possibly keep the run of the proportions adopted by all the manufacturers, he either has to "trust to luck," or else write the name of the firm whose preparation he wishes dispensed. To this direction the prescription clerk pays no attention whatever, but puts in whichever of the different preparations he has "in stock."

The variations often are very great. Thus, a druggist, at the last meeting of the British Pharmaceutical Association quoted the tincture of gelsemium, for example, which, according to a recent article in the *British Medical Journal*, varies in strength from 1 in 5 to 1 in 10, or 100 per cent., and there appears no evidence to show whether the stronger or the weaker is correct. Tinctures of jaborandi, eucalyptus, boldo, etc., may vary similarly. A dozen or more formulæ exist for the syrup known as "chemical food" (the original formula of Parrish not yielding satisfactory results), hence it varies in color, density, acidity, and strength.

Medicinal hydrobromic acid is now largely prescribed, and for its preparation several formulæ have been published. Dr. Wade, who originated the idea of using it internally as a medicine, provides for 10 grains of combined bromine in the drachm; Dr. Fothergill's preparation is about half that strength, and Dr. Squibb's is a purer acid, containing 33.4 per cent. The weaker acid is the one generally used in that country, but it is not that with which the original experiments were made.

Fluid extracts are in the United States so prepared that, as a rule, a fluidounce shall as nearly as possible represent one ounce of the crude drug. In Great Britain both officinal and non-officinal extracts vary so much that when a new drug is introduced half a dozen manufacturers may prepare fluid extracts from it, of as many different strengths; the physician who prescribes and the pharmacist who dispenses it both being ignorant of the exact relation it bears to the drug; and, unquestionably, to a less degree the same holds true of the United States.

To meet the difficulty in France, the Paris Société de Pharmacie, publishes from time to time a series of unofficial formulæ, such as are of most current demand, and which are looked to as assigning a standard strength by all the pharmacists of that country.

As we have in this land the National Pharmaceutical Association, it could do, and in a measure has done, the same thing. But its authority is too little recognized outside of its immediate membership. More frequently

produced editions of Pharmacopœias have been suggested. We have a new Pharmacopœia every ten years, and there is a party who thinks we ought to have one every five years. Professor Maisch and other eminent pharmacists are, however, of opinion, that a new Pharmacopœia every five years would give too much trouble to the pharmacist and the physician, but they propose to meet the difficulty by appointing a standing committee, with power to consider the value of newly introduced remedies, and issue a Pharmacopœia *appendix* every two or three years, and to give a place to the new remedies that proved worthy of survival in the decennial Pharmacopœia.

This, too, would be a practical method of overcoming the difficulty, though it would be, of course, necessary to let the new remedies be dispensed as either of uncertain strength, or else as properties of certain forms for a term of years.

When we add together the almost universal adulteration of drugs, the unavoidable variations brought about by exposure to light, keeping for long periods, and chemical changes, the substitutions effected by prescription clerks, and the difference of proportion, process and quality used by manufacturers, one of the uncertainties in therapeutics is accounted for.

Notes and Comments.

Transverse Fracture of the Petrous Portion of the Femoral Bone.

M. Gosselin, in a recent clinical lecture (*Le Concours Médical*, Dec. 18th, 1880), called attention to a young man who, after a fall on the head, had presented as salient symptoms, at first, hemorrhage, and then discharge of a watery liquid from the right ear, in which the hearing was completely lost. This liquid was abundant, containing little albumen and a greater proportion of chloride of sodium than the serum of the blood. In the space of twenty minutes about two or three grams of the liquid were collected, so that in a day two hundred grams might be discharged. Then, in this case, we have discharge of cerebro-spinal fluid and rupture of the tympanum; again, in order that this may occur, there must be, says M. Gosselin, a transverse fracture, on account of the anatomical conformation of the parts (the arachnoid accompanying the two nerves of the seventh pair forms a cul-de-sac in the internal auditory canal). When there is longitudinal fracture there is rather hemorrhage than clear liquid discharge, and the prognosis is by no means so grave. M. Gosselin has observed twenty-two recoveries in twenty-seven cases, while of four cases of transverse fracture, three terminated in meningo-encephalitis and death.

Effect of Vaccination on Skin Diseases.

Several interesting observations on this subject have lately appeared:—

In the *British Medical Journal*, September, 1880, p. 414, Dr. Drury records several cases in which vaccination was performed during the height of eczematous eruptions in children, with the effect of curing the eczema. Several other observers confirm the value of such treatment from their own experience. In the London *Medical Record*, November, Dr. R. Neale, describes the case of a lady, advanced in years, suffering from a maddening attack of chronic eczema, that had resisted a variety of treatment. Vaccination was performed, and the eczema at once improved, and vanished at the end of the week; whether permanently, remained to be seen. In the *Medical Times and Gazette*, March 1863, p. 283, is a very interesting paper by Dr. Grant, reporting cases of psoriasis palmaris, tinea nummularis, tubercula syphilitica, and psoriasis lepraformis, all quickly and radically cured by revaccination.

On the other hand, in the *Gazette des Hôpitaux*, for last May, Dr. Padieu states that he vaccinated a boy, aged eight months, on the 21st of March. On the 26th of March, at the same time that five vesicles appeared on the arm at seat of inoculation, there appeared on the face and scalp, on parts which were eczematous, a confluent eruption of vaccine pustules. These pustules, about two hundred in number, were entirely limited to the parts which were the seats of eczema. They were attended by great swelling. The child became very ill, but eventually recovered. Eight days after the vaccination of the child, a vaccine pustule developed on the right cheek of the mother, and became very large. Two days afterwards a second, then a third, appeared on the same cheek. On the 3d of April a pustule appeared on the right lower eyelid, then two other very large ones, one on the base and the other on the point of the tongue. These were attended with serious

symptoms. A large vaccine pustule appeared on the 2d of April on the left eyelid of the nurse, a girl aged fifteen, attended with considerable swelling of the eyelids and intense congestion.

The Eucalyptus an an Anti-Miasmatic.

Much and deserved attention has been attracted by the plantations of Eucalyptus, located by the Trappists on the pestilential Campagna, near Rome. A correspondent writes :—

I learned that the malaria, which had hitherto at this spot been singularly pernicious, has of late years become comparatively mild in type. This improvement is attributed entirely to the growth of the eucalyptus trees, which to the number of 25,000 have been planted within the grounds of Tre Fontane. The shrubs are protected by wicker-work against injury, during the first few years of growth, after which they are left to care for themselves. Those planted ten years ago have now reached a height of over thirty feet. The Trappists prepare a spirituous extract and an elixir from the leaves, both of which are strongly redolent of the odor and acrid taste of the eucalyptus. The extract they are accustomed themselves to take daily as a preventive rather than a remedy for ague. When the attack is actually imminent, nothing is found to answer so well as quinine combined with some purgative. My informant was evidently himself thoroughly saturated with malarial poison, the virulence of which in this particular locality may be judged of by the fact that it proved fatal to all the eighteen friars who first attempted to plant the eucalyptus in the district. As it is, the health of the fraternity has so far improved, that all thoughts of abandoning the monastery and the work have now been given up.

Enteric Fever without Lesion of Peyer's Patches.

Dr. J. W. Moore, at a late session of the Dublin Pathological Society, showed the lungs and intestines of a young woman, aged twenty-two years, who unfortunately caught typhus in the hospital when convalescing from a mild but undoubted attack of enteric fever, and whose death was caused on the twelfth day of typhus, and the forty-sixth day from the commencement of the enteric fever, by an intercurrent attack of croupous pneumonia affecting the right apex. The enteric fever was characterized by a typical range of temperature, moderate ochrey diarrhœa, marked splenic enlargement, an abundant crop of *taches bleuâtres* across the back, and a few rose spots. The fever subsided gradually; a temporary intermission, on the twenty-fourth day, being followed by a moderate recrudescence, lasting until the thirty-second day. On the thirty-fifth day the temperature rose abruptly, and within sixty hours an eruption of maculæ appeared. On the forty-third day (the tenth day of typhus), a pneumonia of the right apex showed itself, which proved fatal in about seventy-two hours. The *post-mortem* appearances were, briefly, typical croupous pneumonia of the right apex, very considerable enlargement of the spleen, which was in a state of putrilage. Peyer's patches were indistinct, and apparently perfectly healthy. There was no "shaven-beard" appearance, nor any trace of recent cicatrization. The case illustrated the doctrine of the essential nature of enteric fever, and of the inconstancy of its secondary intestinal lesions.

Dumbness After Measles.

Dr. Van Hassel states, in the *Presse Med. Belge*, that he was consulted about the case of a boy, four years of age, having all the appearance of good health, who, a month before, had a rather severe attack of measles, since when he had lost all power of speech, uttering only some inarticulate sounds. His gestures were abrupt and somewhat choreic. He heard and understood all that was said to him. Since the measles his digestion had been troubled, and there was frequent disposition to fugitive somnolence, with flushing of the face. The pupils were dilated, and there was tenderness over the cervical vertebræ. After some doses of calonel the iodide of potassium was prescribed, and the child was continually exercised in hearing and endeavoring to pronounce monosyllables or short sentences. In a week he was able to articulate some short phrases, the number of words being as yet few; but in a month's time he had completely recovered his usual power of speech.

The Pharmacology of Chloral Hydrate.

M. Dmitrieff, in a recent inaugural dissertation, published at St. Petersburg, states that he has tested the effect of chloral hydrate, both clinically and experimentally. on unhealthy, badly granulating wounds. By excision of a piece of skin in dogs, and infection of the wound with putrefying matter, he produced unhealthy ulcerating surfaces. Some of these he dressed with one or two per cent. solution of chloral hydrate, while the rest were simply covered with

a moist cloth. The first very soon became healthy, and cicatrized before the others. The ulcers, on microscopic examination, were found covered with a layer of micrococci, which disappeared after two or three days' dressing with chloral hydrate. These results were confirmed clinically; and the writer has also shown that an equal quantity of a one per cent. solution of chloral hydrate destroyed, in twenty minutes, all mobility of the bacteria in a putrefying infusion of flesh.

Effects of Electric Light on the Eye.

An unexpected objection to this light arises from its effects on the eye. European observers state that the frequent variations in intensity to which this light is subject give rise to sudden and frequently repeated changes in the pupil, and, consequently, in the accommodation, of the eye. A light of this kind, therefore, causes not only simple muscular fatigue of the eye, but also a considerable degree of blurring and indistinctness of the retinal image. The eye suffers both when the light is too dim and when it is too bright. In the former case, the object looked at must be brought close to the eye to be clearly seen, and an increased accommodative effort is thus called for, which in most instances results in myopia. In the former case the simple intensity of the light produces undue contraction of the pupil, and consequently an increase in accommodative tension within the eye.

Classification of Lung Diseases.

In an address before the British Medical Association, Dr. Octavius Sturges condemned the present accepted classification of lung diseases, and proposed another one. The old arrangement and the one he proposed differ as follows:—

OLD ARRANGEMENT.

1. Pneumonia: acute, lobar, croupous; or acute sthenic exudative pleuro-pneumonia.
2. Broncho, catarrhal, lobular, pneumonia; secondary pneumonia.
3. Chronic pneumonia.
4. Acute (pneumonic) } phthisis.
5. Chronic (pneumonic) }

NEW ARRANGEMENT.

1. Pneumonia.
   Pleuro pneumonia.
   Broncho-pneumonia.
2. Secondary pneumonic consolidation.
3. Pulmonary (alveolar) catarrh.
4. Fibroid phthisis (fibrosis).
5. (Secondary) pulmonary consolidation.

Some of the advantages he claims for this are:

1. It would distinguish by a cardinal term, pneumonia, a disease having well-recognized phenomena, and one which it is important to identify and separate in order the better to observe and record the many points of interest in its natural history, as regards especially its varying frequency and mortality, epidemic prevalence, and response to treatment.

2. It would group together, along with pneumonia, and apart from other inflammations, certain allied conditions—pleuro-pneumonia, broncho-pneumonia—wherein the essential features of the primary disease are maintained with such modification as the names express.

3. It would separate from the aforesaid group, by the use of the word catarrh, other pulmonary inflammations which have no definite or uniform clinical course, but arise in such various associations that no name can be rightly applied to them save one that merely describes an anatomical condition.

Position in Palpitation of the Heart.

In the *Lyon Médical* Dr. Bouchut states that by the assumption of what he terms the "congestive attitude," nervous palpitations, not dependent on organic disease of the heart, may be instantly arrested. His directions are these: The patient stands erect, fixes his lower limbs, and then stoops over rapidly in such a way as to touch his toes with the tips of his fingers. The head thus falls forward, and its vessels are at once rendered turgid. If the hand be now placed on the cardiac region, it will be found that the palpitation ceased, the disordered impulse being replaced by a regular and rhythmical beat, which indicates that the organ has resumed its normal action. It is obvious that this treatment is not applicable to the case of the aged or those who indulge in alcohol, or, in short, those in whom the integrity of the arterial or venous system is doubtful.

Statistics of Cancer of the Breast.

In a communication to the *Archiv für Chirurgie*, Drs. Torok and Wittelhöfer have utilized the large amount of material amassed at the Vienna Pathological Institute from 1817 to 1879, in order to investigate some points of the statistics of cancer of the breast. Among 72,000 bodies there was found cancer of the breast in 366, or about 1 per cent. of the 30,000 female bodies. In 351 instances the side was indicated, this being the left in 144, the right in 161, and both sides in 46. While in 184 cases that had been operated upon there were 105 in which metastases occurred; these were absent only in 41 of 182 that had not

been operated upon. Metastatic secondary cancer occurred most frequently in the lymphatic glands (192), in the respiratory organs (132), and in the digestive organs (139, of which 127 occurred in the liver).

Iodoform in Gynæcology.

Dr. Kurz, in *Allgem. Med. Centralzeit.*, February, 1880, states, that he has employed iodoform, and with excellent results, in the treatment of chronic metritis, perimetritis and perituerine phlegmon, as also in ulcerations of the cervix.

In treating such cases, a tampon may be saturated with a solution of iodoform, one part in ten parts of glycerine, and then introduced; or an ointment of the same strength may be used. These applications are much superior to those of tincture of iodine, as they calm the pain, and even sometimes induce a slight degree of general narcosis.

The iodoform tampon should be introduced twice a week, and at the same time inunctions with an ointment, containing one part in ten, should be made over the abdomen.

Nerve Stretching in Locomotor-ataxia.

This treatment has been tried in Charcot's wards in Paris. According to the late reports, one of the cases continued to improve, and a month after the operation remained free from pain; the gastric crises disappeared, and the motor incoördination, also, nearly entirely disappeared from both sides. Another case, under the care of M. Debove, was operated on; the median and musculo-cutaneous nerves of the right arm were those stretched. After the operation the pains diminished in the right arm and disappeared in the left arm and the lower limbs. The plantar anæsthesia also much diminished in the left side: the motor incoördination improved; walking became possible without support. The patient regained regular sleep, and refused morphia, as his pains "are nothing to what they were."

An Epidemic of Orchitis.

During an epidemic of mumps Dr. Heller observed, in the garrison of Dantzig, a concurrent epidemic of orchitis (*Berliner Klin. Woch.*, 1880, No. 38). There were in all twenty-nine cases, whereas the usual number in a year in the garrison is but two or three. Only two of these twenty-nine had mumps at the same time. The symptoms were characteristic—pain and swelling of the testicle, the skin of the scrotum not being implicated. Fever was present in most cases, lasting four or five days, after which convalescence required about the same length of time. In fourteen cases the left, in twelve the right was implicated, and in the remainder both suffered, but only one at a time. Atrophy of the testicle followed in a number of cases.

Treatment of Paralysis of the Accommodating Muscle.

In case of paralysis of the ciliary muscle (accommodating muscle) and of the sphincter of the pupil, Dr. Yvert recommends repeated instillations of a collyrium of neutral sulphate of eserine and fomentations of aromatic spirits. If needed, electricity may be employed, applied locally, as may also subcutaneous injections of strychnine. If these measures fail, there is no recourse left but palliative treatment, that is to say, the use of convex glasses adapted to the degree of paralysis. Generally, it is only through repeated trials that the defect of refraction can be exactly corrected.

Salicylic Acid as a Foot Powder.

As a protection to the feet, in the Russian army, salicylic acid is used. It is in the shape of a powder, and is a great preventive against perspiring and sore feet.

COMPOSITION.

Acid salicylic,	3 parts.
Amylum,	10 "
Powder of talcum,	87 "

It is applied dry; on a march, daily; in garrison, every two or three days. It takes off the irritating influence of the perspiration of the feet, and prevents, in consequence, the soreness.

In the Italian army aniseed is similarly used, in hot weather.

The Dioscorea Villosa.

A correspondent in Iowa speaks highly of the fluid extract of this indigenous plant in bilious colic, and he relates a very severe case in which a teaspoonful dose gave immediate relief.

The wild yam has long had a reputation as a "colic root." It is mentioned in the appendix of the United States Dispensatory, but as Prof. Stillé remarks, in the last edition of the National Dispensatory, "Time has not added to our knowledge of its properties." He thinks its active principle is allied to ipecac.

Correspondence.

Curious Affection of the Nails.

Ed. Med. and Surg. Reporter:—

A few weeks ago there visited me a young lady troubled with bronchitis. While treating her my attention was drawn to a most peculiar condition of her finger-nails, with a request that I would attempt a cure of the trouble. The affection is of such a character as to make me think it an isolated case. I bring it to the attention of the Reporter and its readers, with the hope that there may be offered a method of cure. The history of the case, little of which will suggest a cure, is as follows:—

Miss H., aged sixteen; with the exception of bronchial trouble, the patient enjoys general good health. Her cheeks are red and her skin fair and unspotted. Both parents are living and well. She has several sisters and a brother, all of whom enjoy good health.

When about thirteen years of age Miss H. was engaged in the warping process in the manufacture of organzine silk. She soon began to notice a change in the appearance of the nail on the index finger of the right hand. The nails appear to have been naturally long and well-shaped. But the one referred to began to separate from the matrix and leave a correspondingly large free edge. This change, which was slow and attended by inflammation and pain, proceeded inwardly from the outer border of the matrix. During these three years the remaining fingers on that hand, as well as those of the other hand, became similarly implicated, the action in each being the same as on the index finger indicated. On some of the nails, instead of the fine parallel lineation generally found on the surface of a normal nail, there are several indentations and irregularities. The nails of both hands have now succumbed to the change, as have, also, two nails of each foot.

The difference between my patient's nails and those of a normal condition, is very striking. The free border is not very thin, nor apparently very brittle; as, though engaged in an employment requiring the steady use of the fingers, none of the nails are broken off. The pink hue of the matrix, as seen through the nail, is fast disappearing. The work in which the patient was engaged was of a poisonous character. She believes that none of the silk was dyed with deleterious coloring matter. Two sisters were engaged in the same work, but neither they nor the rest of the operators have had the faintest change in their nails or fingers: nor have they suffered in any other way from poison.

From boyhood, up, the father had some inconvenience with one toe, arising from the appearance, almost periodically, of a spot of soreness on the nail, which was always followed by an inflammation of the entire nail and its subsequent loss. It is not, however, probable, that any heredity exists between the father's nail trouble and that of the daughter.

The patient has sought advice from various sources, and has used several ointments, and many other forms of treatment, but without avail, as the affection gradually becomes more serious.

The social position of the patient renders the annoyance of having her otherwise well-shaped and comely hand so strangely altered one not to be lightly regarded. But thus far I have not been able to determine a remedy which will be likely to check the disease and cause the nails to cling more closely to the matrix.

If, from what has been stated, any of my brethren can suggest a cause for this singular disease, and a course of treatment, it will greatly relieve my perplexity.

Placenta Previæ—A Forced Delivery at Eight Months—Mother and Child Saved.

Ed. Med. and Surg. Reporter:—

Mrs. E. H., æt thirty-eight years, a strong woman, the mother of nine children, all natural presentations—but most labors were severe and children had to be delivered with instruments—became pregnant about the first of May last, and was perfectly well up to December 6th, when she was suddenly seized with quite a profuse flow of hemorrhage from her womb, which, however, soon ceased of its own accord, and she continued to do her usually heavy household work; but a few days later she complained of malaise, a sense of weight and of numbness in the pelvis, etc.; she was suddenly aroused in the middle of the night by the escape of blood from her genital parts. When I was first consulted, the hemorrhage, which was but moderate, had soon ceased. and as the woman was not plethorous, I did not perform venesection, merely recommended the horizontal position, rest, restricted diet and cool, acidulated drinks. She was soon up and about, to be again taken with hemorrhage, which was readily stopped on resuming the recumbent position. She had quite frequent attacks of a similar nature, but always in moderate amounts. up to the night of January 1st, when I was very hastily summoned to her bedside. Hemorrhage now very profuse indeed; vaginal or digital examination revealed uterine orifice almost completely closed, and the child very high up. I now advised absolute rest in the horizontal position, emptied the bladder per catheter, with elevated hips, refrigerants, etc., and administered vinum ergotæ ℥ss, in three doses, at intervals of ten minutes, which had a very salutary effect upon the hemorrhage, when I left my patient. Was called again at noon the same day, when I found the flooding had become much more profuse, but no uterine pains or contractions had manifested themselves all the time. I now found the orifice slightly more dilated. Demanded a consultation. Dr. K. was now telegraphed for, but replied that he had another engagement and could not possibly come. I now had to choose between two resources, the tampon and rupturing the membranes. I chose the latter. I now administered several (gtts. xxx) doses of ext. ergotæ fld., applied frictions over the abdomen, introduced my index finger into the

uterine orifice, tittillating the os, and attempted to dilate the same. I soon found the parts became dilatable by these manipulations, interrupted by intervals of rest from time to time. She now experienced slight pains; slight contractions followed. I found the membranes becoming tense and engaged at the upper part of the cervix; these I soon ruptured. The head being the presenting part, I carefully pressed it up with the finger, so as to permit all the liquid to escape, when soon all hemorrhage ceased. Woman now felt several pains, bringing down the head into the excavation of the pelvis, and the soft parts being perfectly dilatable by this time, I found the flooding had been caused by an insertion of the placenta over the posterior orifices of the internal cervix. I applied the forceps and delivered the child very hastily, which, much to the surprise both of myself and family lived(having been asphyxiated but soon commenced to breathe). Both mother and child were,as a matter of course, very weak, but are doing admirably well at this writing, and may be fairly considered out of danger. W. P. KISTLER, M.D.

Schencksville, Pa.

Open Confessions.

ED. MED. AND SURG. REPORTER:—

In some recent numbers of your journal articles have appeared on the above subject, and *apropos* of the same I do not hesitate to unburden myself also.

About a year ago, I was excitedly "rung up" at two o'clock in the morning, by Mr. W., announcing that "his wife was vomiting blood, urging me to hurry, before she was dead." Without making the usual stereotyped inquiries, I immediately responded, and was soon at the bedside of Mrs. W., whom I found blanched and well nigh pulseless, at intervals giving a short hysterical cough, and scarcely able to articulate, by reason of dyspnœa. The room was crowded with anxious friends of both sexes, and in a room adjoining I was shown a large pool of blood upon the floor, as one of the voluble females present expressed it, "just as she had thrown it up."

Not being the family physician of Mrs. W., although a regular attendant upon her husband, I had, during a previous visit to him, been consulted by his wife concerning her weak lungs, and the propriety of taking cod-oil therefor; and owing to her present exhausted condition, I asked no further question, but at once began administering ergot and iron,with applications of ice bags to the chest, followed by much apparent benefit, leaving her, an hour or so later, quite comfortable, announcing that, inasmuch as I had been called in an emergency, I would turn the case over to her own physician, and would not repeat my visit.

Some months later one of the ladies who was present on the evening of the hemorrhage rather knowingly asked me "What was the matter with Mrs. W.?" and, of course, I responded "hemorrhage from the lungs." Assuming a still more wise appearance, with a twinkle in her eye, she said, "Well, doctor, the blood did come from her body, *but not from that end*—she had a *miscarriage*. Exit M.D. Who will cast the first stone? A. T. VANVRANKEN.

West Troy, N. Y., Jan. 20th, 1881.

A Query in Ethics.

ED. MED. AND SURG. REPORTER:—

I am not in the habit of writing articles for publication, nor do I now propose to ask much of your valuable space for such a purpose. As a good deal has lately been written about bogus colleges and the diploma traffic, I would call your attention to another subject somewhat germane, I think, to those just mentioned.

There are some highly respectable medical colleges in our land who propose to receive a certain number of worthy, poor, young men, whom they call "privilege students," at a less rate of tuition than they charge others. They send out their private letters and also publications to the physicians of the country,asking their coöperation in the good work of educating the "worthy poor" who are to be known only to the professors of the college as "privilege students."

Now, this may be all good enough in itself, but I ask if it is in consonance with the ethics of our profession for these same philanthropic and charitably disposed college professors, when one of these privileged ones is so unfortunate as to get sick in their midst, to charge him the regular fee for prescription and attention that they are in the habit of charging their patients ordinarily. Surely "the legs of the lame are not equal."

I may not be abreast of the times on this subject, having graduated in medicine a quarter of a century ago, but one thing I do know, the professorship in my "alma mater" never charged a medical student, rich or poor, for prescription or attention when sick. If I am behind the advanced ethical position of the profession, as indicated by these luminaries, I would like to know it.

ENQUIRER.

[We should entertain a very small opinion of any Professor who would charge a student for professional services.—ED. REPORTER.]

Substitute for Tobacco.

ED. MED. AND SURG. REPORTER:—

In looking over the back volumes of your Journal, I noticed in January 3d, 1880, number, a question by a Dr. B. L. L., of Illinois, asking, "Is there any harmless substitute, or drug, which will induce a distaste for tobacco?" And in reply, would say, that about eighteen months ago I was attending a young man who had used tobacco to such an extent that it was affecting his nervous system, and having used it for a number of years he found it difficult to do without something to chew, as he stated it, when I suggested that he try common chewing gum for a while, until his system could rebuild itself again. After having used the common gum (that is, no particular make), for two or three weeks, he has had no desire for tobacco, and has not taken a chew since he first began using the gum.

In the last six or eight months I have recommended it to several tobacco chewers (one of

thirty years' standing), with like success, and I begin to think it is a cure that at least only costs a trifle to try it, and is not an unpleasant experiment. I am sincere when I say to the medical profession that it is the nearest a harmless, and I think, a successful, antidote for tobacco of anything that we have ever had.

It was discovered by the merest accident, and by giving it to the profession I am desirous of hearing of their failures and successes elsewhere with it. FRANK B. BULLARD, M.D.

Chesnut, Illinois, January 14th, 1881.

Letter from Southern Illinois.

ED. MED. AND SURG. REPORTER:—

Southern Illinois seems to be seldom represented in the columns of the REPORTER, although we know that it has many readers in this locality. This lack of representation in your columns does not arise from inactivity, or want of due appreciation on the part of the profession here, for a more active, wide-awake, intelligent set of medical men cannot be found in any other locality.

We have just returned from the regular annual meeting of the Southern Illinois Medical Association, held at Du Quoin, where the above assertion was fully verified.

This Association now numbers about two hundred members, which includes about every medical man worthy of recognition in its legitimate territory, and is doing a good work for itself and the cause of medicine. It was one of the active factors in originating and promoting the existing medical law in the State, which is quite generally commended for its thoroughness and efficiency. The Association is one of the strongest medical organizations in the State, and its transactions will compare favorably with those of any other in the country.

The medical law above referred to has done much to purge the ranks of the profession of the illiteracy and incompetency that hitherto encumbered it, but unfortunately, the last clause of the act—its caudal appendage, we call it—permits men who have practiced, or pretended to practice, ten years in the State to continue unmolested, regardless of their good, bad, or indifferent qualifications. We personally know of two men who are using that privilege, so illiterate that they are not only unable to write their own names, but fail to read the plainest English print. However, our efficient State Board of Health refuse to give such practitioners certificates, and they are thus practically ostracised by the profession and the more intelligent communities.

It is hoped that our State Legislature, during its present session, will perform a capital operation by amputating the aforesaid caudal appendage to the otherwise satisfactory law regulating the practice of medicine in the State.

JAMES I. HALE, M.D.

Anna, Ill., Jan. 25th, 1881.

—A New York dealer in bad milk has been fined $150, and it is suggested that if the law is generally enforced the city will realize sufficient in fines to pay the interest on its debt.

NEWS AND MISCELLANY.

Experiments in Hypnotism.

Dr. Wm. A. Hammond recently delivered an interesting lecture on this subject, in the New York University Medical College, from which we allow ourselves a few extracts:—

He stated that persons could be put in a hypnotic condition through different senses, but a simple way was to hold a piece of glass before a subject—glass from a chandelier, for instance—and he would pass into a hypnotic state. This faculty was not confined to men and women, but existed also in animals.

Last summer, continued Dr. Hammond, I hypnotized crabs in Fulton Market. I stroked a dozen of them and soon had them all standing on their heads. You could then have clipped off their fins and they wouldn't have known it. You can hypnotize a frog, and, laying him on his back on the palm of your hand, rip him open with a pair of scissors and it won't hurt him. Mr. Bergh might try to stop such an experiment, although I think he hasn't the power to do it. I have a hen here that went into a hypnotic state yesterday without having anything put before her to look at.

Dr. Hammond then took a hen out of a bag and pressed her head down on the table; she remained motionless. He said hypnotism was not a good name for the condition he was describing, as it was not an induced sleep, but a condition capable of being effected by the mind of another person. He suggested the word "suggignoskism," which he had worked out with fear and trembling, as expressing the condition of agreeing with some other person's mind.

H. S. Gray, a slight, light-haired man, was then chosen from among the subjects for the first experiment. Dr. Hammond held a piece of glass before his eyes, and he followed it around the room as if it were a magnet.

"You have read of serpents charming birds," said Dr. Hammond. "It is the same principle as this. The glittering eyes of serpents hypnotize the birds."

"Look here," he continued, bringing a bottle quickly to the subject's face. "Here is a pretty girl. Ask her to take a walk with you."

Gray gazed at the bottle with admiration, and, encircling it, strutted up and down the room, requesting of his imaginary companion the pleasure of an extended promenade. Dr. Hammond ran a needle through Gray's skin, and left it sticking in his hand, but Gray was wrapped up in the young girl.

"That's not a young girl," exclaimed Dr. Hammond, taking the bottle from him, "it's an old woman, seventy-five years old, if she's a day."

Gray recoiled quickly, and a look of intense disgust overspread his features. He was next given a slice of lemon to eat, being told it was a Florida strawberry. He pronounced it excellent, and then munched a piece of aloe, which he was informed was chocolate caramel, with great relish. A sulphur match was burned under his nose. Dr. Hammond said it was cologne that he was smelling.

"It's first-rate cologne," answered Gray, "although it's pretty strong."

Ammonia was placed to his nostrils, and he was informed that it was water. He poured some on his hands, smelled the liquid, and said it was undoubtedly water. A number of other experiments illustrating this condition were made.

Chemical Examination of Drinking Water.

We quote the following from the *Bulletin* of the National Board of Health :—

A careful study of the chief methods in use for the chemical examination of potable water, so far as organic matter is concerned, has been undertaken by order of the National Board of Health. It is particularly requested of the correspondents of the Board, of medical men throughout the country, and of others interested in sanitary matters, that any well-marked case of disease which may seem, on medical grounds, fairly attributable to organic impurities in drinking water be promptly reported to Dr. J. W. Mallet, University of Virginia Post Office, Albemarle County, Virginia, with a few lines stating clearly the medical nature of the case, and the character of the evidence on which the water in question is suspected of having actually caused disease in persons who have used it.

It is further desired that a sample of each such water be forwarded for examination, but not until notice has been received from Dr. Mallet that the analysts are ready to proceed with it, since it is important that no useless delay should occur between the shipping of the sample and its investigation in the laboratory. In notifying any one who may be able to furnish specimens of suspected waters that may be forwarded, clear instructions will be sent as to the quantity of water required, and the mode of collecting, packing and shipping it.

It is particularly desired that no case be presented on doubtful or vague evidence, since one important object of the inquiry demands that all such be rejected, and only those cases examined which involve the strongest grounds for believing that mischief has really been caused by organically foul drinking water.

The cost of packages and transportation for samples will be borne by the Board of Health.

The Medicine of the Talmud.

A French writer gives some curious extracts from the medical portion of the Talmud. Most of the opinions expressed by its authors indicate, as might be expected, very imperfect observations. For instance, they believed that the urethra presented throughout its length a fine septum which divides it into a spermatic and a urinary canal. They believed that by long retention of urine this septum might be rent, and a fistulous opening between the two canals result—a "spermatico-urinary fistula"—which would render a man sterile. Hence they drew the useful lesson that there should be no avoidable delay in micturition.

The physiology of the Talmud is grotesque enough in some particulars. "The kidneys give advice, the heart understands, the tongue produces articulate sounds, the mouth completes them, the œsophagus receives and rejects food, the trachea produces the voice, the lungs absorb liquids, the liver is the seat of rage, and the gall-bladder throws bile upon it and calms it, while the spleen is the seat of laughter." Among other duties of the learned doctors was the superintendence of the slaughtering of animals. Arguing from their physiological knowledge that the trachea and œsophagus are the structures most essential to life, they ordered that all animals should be slaughtered by the division of these only. A certain Rabbi, having observed that this was not a very speedy mode of death, suggested the division of the blood vessels of the neck, but his advice was overruled.

The therapeutics of the Talmud consist almost wholly of hygienic rules, although one sage recommended bleeding every thirty days, as a preventive of disease, and he also indicated certain days of the year and week on which venesection was most advantageous. The opinion ascribed to Rabbi Banaah may, perhaps, have been general. He said: "Wine is the best of remedies; it is only where there is no wine that drugs are necessary."

The Night Medical Service in New York City.

Dr. Henri Nachtel, to whom is due the night medical service in New York City, has just addressed the Academy of Medicine, in Paris, in regard to our system of ambulances. Dr. Nachtel, who has thoroughly studied the method of transporting those suffering from accidents in New York to the hospitals, is loud in his praises of the rapidity and efficiency with which the system is carried out. In France, the method of transporting the wounded through the streets seems to be of the most primitive kind. In Paris, when a wounded or ailing man is found, policemen take charge of the person, and he is carried to the nearest apothecary. Though Police stations abound in Paris, a person suffering from an accident is never carried there. A litter has to be hunted up, and then porters found, who transport the person either to his house or to the hospital. Before all this can be accomplished, minor accidents, for want of immediate attention, become of the most serious character. Dr. Nachtel thinks even that deaths frequently occur in Paris from want of celerity in the transporting of patients. In dwelling on the many advantages of the New York ambulance system, Dr. Nachtel expressed the hope that our method might be adopted in Paris. A commission, composed of MM. Larry, Legouest, Vulpian, and Chereau, was appointed by the Académie de Medicine to study the whole subject. It will be pleasant to know that Dr. Nachtel has been the means of introducing into Paris the New York ambulance system.

Shall We Shave or Not Shave?

It seems, from a note in the *Lancet*, that the tendency in England is to go back to the shaven faces of our ancestors. That journal writes on the hygienic aspect of the question as follows:—

"We fear the laborious argument that it was healthful to man to spare himself the trouble of shaving was somewhat strained, and that the wish for a fashionably formidable appearance was father to the thought of healthfulness as regards the wearing of beards and moustachios. The number of persons returning to the old English practice of shaving both the chin and the upper lip is noticeably increasing, and there is certainly much to be said for the clean and orderly character of the result. It is, at least, a remarkable circumstance that throat affections have not died out, or, we believe, sensibly diminished, since the custom of growing the beard became general. It must, in the long run, be a matter of personal predilection whether a man shaves or leaves his face embellishment to nature. It is practically, in this case, as in most others, idle to seek an argument in favor of the vagaries of fashion in the code of health laws."

Born Bearded.

The chief magistrate of Nicoya, Costa Rica, records, with all seriousness, the birth of a monstrosity, a five-months' child, possessing marked and exceptional features. This diminutive and curious infant is fully bearded and has two small teeth on the lower jaw, and appearances indicate the coming of two on the upper one. The following are the dimensions of the infant: Length, 14 inches; thickness, 6 inches; thickness of arm, 1½ inches; calf of leg, 2¾ inches; length of foot, 1⅞ inches; circumference of cranium, 9¾ inches; circumference of neck, 5 inches. A "noble ancient" in a child of five months is refreshing, and Costa Rica is entitled to the palm for extraordinary additions to the vital statistics of the world.

Pharmaceuticals.

HORSFORD'S ACID PHOSPHATE.

Within the last year we have prescribed this preparation in a number of cases, and have been highly pleased with its positive tonic effects. It has seemed to us especially active where there was a considerable languor of the nervous system, and defects in nutrition. In the miasmatic maladies of childhood its influence was prompt and gratifying.

BAKER'S COD-LIVER OIL.

No purer oil is to be found in the American market than this. It is received monthly, in air-tight cans, from the Halten Islands, Norway, the whole production of which is engaged by this energetic firm. It is sold pure and combined with malt, and also in emulsion. From the observations we have made of its effects on various patients, we can recommend it as fully possessing the therapeutic qualities of this alimentary drug.

High Potencies in Homœopathy.

The follies of homœopathy are beginning to be seen, even by the followers of Hahnemann. At the recent meeting of the Homœopathic Medical Society of New York, Dr. H. M. Paine had the candor and boldness to say:—

"Our experience in the use of high potencies is based, as Hahnemann's was, on theoretical grounds only. It is one of the most singular forms of idealism ever seriously entertained by the medical profession. I firmly believe that when our reputed cures are reported in connection with all the cases treated, we shall find that their frequency is not greater than those of daily occurrence without the intervention of medicine of any kind."

The Metric System.

A correspondent—one of many—writes us "I would most earnestly request that you *always* give the weights and measures in the old system (put the metric equivalents in brackets if you choose). I think after this year I will subscribe to such journals only as give the old system."

Our own views on this subject are well known; we have not believed the metric system adapted to the medical practice of this country; but we do hold that every physician should be sufficiently familiar with it to be able readily to convert the one into the other method of measurement.

Fatal Military Etiquette.

The following singular case is reported in the daily papers:—

Archibald Gibson, Second Lieutenant of the Seventh U. S. Cavalry, died January 26th, 1881, in St. Louis. The cause of his death was inflammation of the brain, believed to be the consequence of an accident which happened while he was at West Point. One day, on parade, a spider got into one of his ears. Under the rules he could not raise his hand, and he stood in the ranks for more than an hour, while the insect worked its way inside. When dismissed, Gibson's ear was full of blood, and it was two days before the insect could be removed. Corrosion of the internal bone followed, and after suffering severely from sickness while on duty with his regiment in Dakota, he went home expecting to resign, but as it proved, to die.

The Philadelphia County Medical Society.

A meeting of the Philadelphia County Medical Society was held January 19th, at the hall, Thirteenth and Locust streets. The following named gentlemen were elected officers for the ensuing year: President, Dr. A. H. Smith; Vice Presidents, Drs. H. Y. Evans and C. H. Mills; Recording Secretary, Dr. H. Leffman; Assistant Recording Secretary, Dr. J. D. Nash; Reporting Secretary, Dr. Frank Woodbury; Treasurer, Dr. W. M. Welsh; Corresponding Secretary, Dr. J. B. Roberts; Librarian, Dr. M. O'Hara; Censor, F. P. Henry. Delegations to the American Medical Association at Richmond, Va., and to the Medical Society of the State of Pennsylvania, at Lancaster, were also elected.

Mr. Sothern as a Physician.

The late eminent comedian was designed by his family for a surgeon, but after witnessing an operation in one of the London hospitals he be-

came disgusted with his destined profession, and next turned to the study of theology, with the object of entering the English Church. A chance participation in amateur theatricals, when he assumed the character of Othello, decided his choice of profession.

German Eye and Ear Infirmary.

For the year 1880 there have been gratuitously treated at the German Eye and Ear Dispensary, 441 North Fifth Street (Dr. M. Landesberg, Surgeon in charge), 1190 patients, of which number 828 were for eye diseases, and 361 for ear diseases. The number of important operations performed in the Institute were 111, of minor 153.

Items.

—The Camden Dispensary, last year, treated 2453 cases, of which 101 were smallpox.

—Positively the last of General Washington's servants died last month, in Washington. This was Sally Hunter, who was one of the slaves manumitted in his will. She was born—so it is said—on his estate, in 1766, and hence was 115 years old. It is about time for these famous freedmen to become extinct.

OBITUARY NOTICES.

—The death is announced of Dr. Julius Vogel, from cardiac rupture. The deceased was director of the Medical Clinique, and Professor of Special Pathology and Therapeutics at Halle.

—Dr. J. L. Vattier, of Cincinnati, died in that city, January 13. He was the oldest physician born on the spot and one of the oldest inhabitants, having first seen the light Oct. 31, 1808, close to the river, on Broadway. He was highly respected as a citizen and physician.

—Dr. John Edwin Alvord, of Berwick, Pa., closed his life on New Year's day, 1881. He was born in Illinois in 1845, received his diploma at the Jefferson Medical College, and won an enviable reputation in the community where he resided.

—Dr. Charles McDermont, formerly Surgeon-General of Ohio, and one of the most prominent surgeons in the Army during the war, died at Dayton, Ohio, January 7th, from rheumatic troubles contracted during the war.

—Dr. William Darrach died January 28th, at his residence, in Germantown. He was born in this city in 1839. He was educated at the University of Pennsylvania, from which he graduated B.A. in 1859 and M.D. in 1861. He established himself in general practice in Germantown, and continued there until his death. Dr. Darrach was a member of the Philadelphia College of Physicians and Surgeons, of the Philadelphia Pathological Society, and of the Society of the Alumni of the University of Pennsylvania. During the war of the rebellion he served as an Acting Assistant Surgeon in the United States army, and was on duty for several months at the McClellan United States Army General Hospital, in Germantown.

QUERIES AND REPLIES.

Dr. J. H. P.—"Bartholow on Hypodermic Medication." Price $1.25.

Sicurus.—We have looked up the matter, but can find no definite description of the plant called *hermodactyl* by the ancients. Many of these old names have not been identified.

Dr. S. K., of Pa.—We can furnish complete sets of the REPORTER from 1858.

Drs. B and M., Ohio, send us a formula for Tully's powder:—

℞. Cretæ prepar.,
Pulv. camphoræ,
Extract glycyrrhizæ, aa 5xxxiij
Morphiæ sulphatis, 5j. M.

Dose, 5 to 10 grains.

Dr. W. L., of California, writes: "If your Middletown, N. Y., correspondent had poured quicksilver on the gold ring that was on his patient's penis he could then have easily broken the ring with his fingers. He would thus have relieved both the patient and jeweler of considerable embarrassment. I hope he will try this plan on the next case of the kind he meets.

H asks: "How is it necessary to proceed in order to get the appointment of resident at the Philadelphia Hospital? What are the duties of Resident at that institution? Is it necessary to undergo an examination?"

Ans.—The appointments are made annually, after an examination. The duties are professional only. Political or social influence is not wholly without effect in securing the appointment.

MARRIAGES.

DOWNEY—MUSSELMAN.—At the residence of the bride's parents, Topeka, Ill., on Thursday, Dec. 23d, 1880, by Rev. W. C. Avey, John W. Downey, M.D., and Mary Alice Musselman.

MILNER—WETHERILL.—On January 12th, 1881, at the residence of the bride's parents, near Kennett Square, Pa., by Friend's ceremony, R. Hamilton Milner, M.D., of this city, and Sallie R., daughter of Issac Wetherill.

RHEA—WADE.—At the residence of the bride's parents, in Bristol, Ohio, on the evening of December 29th, by the Rev. E. B. Wakefield, Dr. A. H. Rhea, of Sharpsville, Pa., and Miss Mattie Wade, of the former place.

VAN MATER—AARONSON.—At Columbus, New Jersey, January 13th, by the Rev. H. R. Hall, Dr. D. G. Van Mater, and Susie, daughter of Robert Aaronson, Esq., all of Columbus.

DEATHS.

BRAUN.—Dr. Louis Braun, December 30th, 1880, of broncho-pneumonia, aged fifty-five years and six mos., at Elizabeth, N. J.

FITHIAN.—At his residence, in Woodbury, N. J., January, 8th, 1881, Joseph Fithian, M.D., in his eighty-sixth year.

FLEMING.—In this city, suddenly, on the 17th inst., D. Lambden Fleming, M.D., in the forty-second year of his age.

SELLERS.—In this city, January 5th, 1881, Hiram F. Sellers, M.D., aged forty-five years.

NESMITH.—At Paris, on December 23d, 1880, Dr. Robert Dilnon Nesmith.

TERRELL.—Wednesday evening, December 29th, 1880, at the residence of his father-in-law, at New Vienna, Ohio., of consumption, Dr. P. M. Terrell, aged thirty-seven years.

THRELKELD.—Wednesday morning, 12th inst., at his late residence, near Visalia, Ky., Dr. Wm. Threlkeld, in his sixty-seventh year.

Smithsonian Institute.

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

Trade supplied in Philadelphia by

1215-1267eow ROBERT SHOEMAKER & CO.

J. C. BAKER & CO'S. COD-LIVER OIL.

Absolute Purity and Freshness.

Secured by Specifying our Brand.

Prepared on the **HALTEN ISLANDS, NORWAY**, with great care, from the finest selected livers of **NET-TAKEN COD FISH**, at a season of the year when they are in their highest condition.

PRIZE MEDAL—PARIS, 1878; BERLIN, 1880

BAKER'S EMULSION

With Hypophosphites of Lime and Soda, containing fifty per cent. Pure Oil, is a perfect and potent preparation.

☞ We employ Baker's Cod-liver Oil in preference to all others. The Pure Oil is palatable and digestible, and the Emulsion is well nigh delightful.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O	
Quinidia do	15 "	20	24	2	2	
Cinchonidia do	15 "	C	H	N	O	
Cinchonia do	15 "	20	24	2		
Chinoidine Purified,	30 "					

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

Lecture.

VAGINAL FISTULES.

BY WM. H. WATHEN, M.D.,

Professor of Obstetrics and Gynæcology in the Kentucky School of Medicine, at Louisville.

REPORTED BY A. H. KELCH, M.D.

This morning we will consider the classification of fistulous communications with the vagina, together with the symptoms, diagnosis, etiology and treatment.

We may have vesico-uterine fistules, vesico-utero-vaginal fistules, vesico-vaginal, urethro-vaginal, recto-vaginal and perineo-vaginal fistules; also uretero vaginal and uretero-uterine fistules.

A knowledge of vaginal fistules is of much greater importance to the practitioner now than formerly, from the fact that with the present improved methods of operating we can, in nearly every instance, permanently relieve these patients, and bring about a restoration of the natural condition, without impairing to any great extent the function of copulation and reproduction. The symptoms of these fistulous openings are usually sufficiently diagnostic to enable us to diagnose that there is a communication from some of the adjacent pelvic organs connecting with the vagina; but the subjective symptoms are not pathognomonic, nor are they sufficiently diagnostic to enable us to say from where the particular opening enters into the vagina. The most important of all the symptoms is either a discharge from the vagina of urine or fecal matter, the latter of which is pathognomonic of recto-vaginal fistule. But with the former this is not the case, for we may have a constant passing of urine from the vulva, so that the bladder is kept empty, when there is no fistulous opening connecting the bladder with the vagina, the condition being simply the result of inability on the part of the woman to retain her urine, and it dribbles away through its natural channel. These are most of the subjective symptoms that your attention will be called to. The dribbling of urine or the passage of fæces from the vagina may begin immediately after labor, or more usually not until the third to the tenth day, and then it continues constantly, until the fistule is cured.

It is unnecessary to call attention to the great annoyance and inconvenience that result from the constant passage of urine or fecal matter through the vagina, so I will now pass on to the diagnosis of the fistulous openings by a physical examination. By availing ourselves of the objective symptoms, we can usually arrive at an accurate diagnosis with but little difficulty. Where the opening is large and connects directly with the vagina, by a digital examination we will be able to ascertain its locality and dimensions. Where the opening is small and connects directly with the vagina, whether a vesico-vaginal, urethro-vaginal, recto-vaginal, or perineo-vaginal fistule, we can detect usually a little elevation that marks the position of the opening. But where it is a uretero-uterine fistule, or where the cervix uteri is involved, we will very often experience considerable difficulty in completing the diagnosis. Where we are not able to make the diagnosis by digital examination, we may combine with it an instrumental examination. By the use of the finger in the

vagina and the sound in the bladder we may be able to bring the sound through the opening into the vagina, against the finger. Or, with the finger in the rectum, and a sound in the vagina, we may be able to diagnose an opening beween the rectum and the vagina. Or we may expose the vagina with Sims' speculum, so as to see the entire vaginal surface, and detect by this means the opening in the vagina. Every part of the vaginal surface can be exposed where the vagina is not contracted and misshapen by cicatricial bands, and in this we may be able to see the opening of the slightest fistule. Now when we are unable to make the diagnosis by the combined digital and instrumental examination, we fortunately have other means at our disposal. We may inject the bladder or the rectum with colored water, and by having the vagina exposed and reflecting light into it, we can see where this colored liquid comes through the smallest-sized fistulous opening. If it is in the anterior vaginal wall or the regular vesico-vaginal fistule, we can see the colored liquid coming through, drop by drop, in that locality. If it be a vesico-utero-vaginal fistule where the opening comes from the bladder into the neck of the uterus and down through its tissue, we will see, usually, just at the anterior edge of the cervix, the colored liquid dripping down into the vagina. If it be a vesico-uterine fistule, where the opening connects from the bladder above the vaginal attachment into the cervical cavity, we will find the liquid coming down into the vagina through the cervical canal. But where it is a uretero vaginal or a uretero-uterine fistule, then we cannot make the diagnosis in this way, and about the only means of doing so is by the exclusion of the other varieties. When we find that the urine constantly dribbles away, and by no means at our disposal are we able to find any communication between the vagina or uterus with the bladder, then by exclusion we could diagnose a uretero-vaginal or uretero-uterine fistule.

The idea prevails largely with the general profession, that fistulous communications with the vagina generally result from instrumental interference in labor; but the investigations of leading gynæcologists have now conclusively demonstrated that, so far from this being true, the timely use of instruments to speedily deliver the woman often prevents sloughing, and consequently fistulous openings. Practically speaking, fistules resulting from other causes than labor are of little interest to the physician; however, we may meet with occasional fistules caused by cancerous, syphilitic or other forms of ulceration, or from whatever may penetrate through the walls of the vagina into an adjacent viscus.

The fistules caused during labor result from the pressure sustained by the parts between the bony structures of the mother and the head of the child, the pressure being so great that the circulation is cut off for a sufficient length of time to cause death of the parts; which, of course, is followed by a slough. As long as the child's head recedes after each pain there is comparatively little danger of serious injury to the maternal structures, but when the resiliency of the parts has been so destroyed that there is no recession of the child's head, then there is great danger of serious lesions, and unless the labor is promptly terminated there will almost invariably result a fistulous opening. A distended bladder may be the cause of a fistule, by obstructing the passage of the child and retarding the labor. It is at least a too frequent cause of vesico-vaginal fistule, and it is unfortunate that the general profession pays too little attention to emptying the bladder during labor. True, owing to the extreme pressure, it is sometimes next to impossible to introduce a catheter; but this difficulty can usually be overcome. If it cannot, it is much better that the child's head should be removed from its impacted condition against the urethra, by the use of the forceps, and if this be impossible, to even aspirate the bladder immediately above the pubes, than to allow it to remain distended. It may be observed that in those cases where the forceps has been used the women have been in labor much longer than in cases where the delivery is effected by the efforts of nature. It may be further stated that in those cases resulting after the use of forceps the destruction has been less than in those where no instrumental interference has been resorted to. The duration of the labor may, in general terms, be said not to affect the degree of the injury.

The urine may pass immediately after the passage of the child's head through the vulva. This is particularly true of cases resulting from a distended bladder, either caused from laceration or sloughing. In the majority of instances there is no passage of urine through the vagina until from two or three to ten days after labor. The majority of all cases of vaginal fistules occur in the primipara.

The history of vaginal fistules, we find, until quite recently, presents few successful operations for this distressing malady.

We find that a German physician, about 200

years ago, called the attention of the profession to the treatment of these fistules, and described the methods of examination and the operation for their cure, but it passed out of the knowledge of the profession, and nothing more was heard of the successful treatment of them until 1829, when Dr. H. S. Levert, of Mobile, Ala., in the May No. of the *American Journal of Medical Sciences*, called attention to the use of the silver suture in the treatment of vaginal fistules. In November, 1834, M. M. Gosset, in a letter to the London *Lancet*, called attention to the successful operation for a vesico vaginal fistule, the result of impaction of a stone in the bladder, in which he united the edges of the fistule by the interrupted silver suture. We find, then, that Neetzler, of Germany, in 1846, describes the clamp suture and the method of denuding the tissues by the bistoury or scissors, and speaks of a speculum essentially the same as that devised by Sims. We find, again, that between 1836 and 1840, Hayward, of Boston, had succeeded with the silk suture. Also, in 1847, that Dr. Mettauer, of Virginia, called attention to a successful operation by the use of lead sutures; but these successful operations were not brought prominently before the profession in this or any country, until the time of Dr. Sims, who, in the *American Journal of Medical Sciences*, in 1852, first published to the world his successful operations with the metallic sutures, claiming that nearly every case of fistule into the vagina can be permanently relieved by properly denuding the edges and bringing them together with silver sutures. He first used the clamp suture, but subsequently abandoned this method and united the edges by the interrupted silver suture. Whether Sims was familiar with the views of those who preceded him or not, he certainly deserves the greatest praise for having brought this operation so prominently before the profession that it is now considered one of the successful operations in surgery, instead of being almost invariably ignored or condemned, as in the past. The question has been discussed very freely by the profession, whether the success of the operation is due to the metallic suture or to some other cause.

Dr. Sims' belief was that before the time of his introduction of the metallic suture into practice, the reason of the failure of previous operations was because the organic suture caused suppuration in its track, thereby preventing the union of the denuded edges. It has now been proven that whether we use organic or metallic sutures the operation may be almost equally successful, and it has been conclusively demonstrated that the success of the operation depends not so much upon the quality of the suture as upon the preparatory treatment, and the method of denuding the edges and bringing them properly together. There has been really very little improvement in the methods of performing the operation since Sims first published his researches, and he has written but little on this subject since. The treatment advised by Sims, and generally followed, is to thoroughly denude the edges of the fistule and bring them together with the intercepted silver suture, twisted tight enough to cause perfect coaptation, but not suppuration by strangulation. The patient must then be kept perfectly quiet, with the bowels bound, having the urine passed through a sigmoid, or some form of self-retaining catheter, with the woman in a horizontal position for ten or twelve days. These have been considered prerequisites to success in every instance; but we find that Prof. Simon, of Heidleberg, operates by bringing the edges together with the silk suture, and permits the patient to walk about, allows the urine to be passed as usual, as if no operation had been performed. He has achieved a wonderful success. He stands, however, nearly alone in his treatment. I myself doubt whether the custom of confining these patients to bed and having the water drawn by the catheter and the bowels bound is any better than his method. I would, in any event, after introducing a self retaining catheter, adopt Prof. Simon's practice of not confining the patient to bed. Some operators do not even permit the patient to turn upon her side. A case upon which I operated some fifteen months ago was one of the most unfavorable that could be imagined. After the operation, the edges being united by twelve sutures, the woman was constantly nauseated and attempting to vomit; finally had severe spasms for thirty six hours. In the course of the third day she got out of bed and walked around the room. She made a perfect recovery.

One of the greatest improvements in the treatment of fistules is the preparatory treatment, which was first recommended and practiced by Dr. Sims and Dr. Bozeman—more efficiently by Bozeman. It has been my experience that if thorough preparatory treatment be practiced and the patient brought into a fit condition to be operated upon, it matters little, if the edges be well denuded, whether they be brought together by metallic or thread sutures; whether the woman be confined to bed or allowed to walk about the room; whether she wear a catheter constantly or have the urine regularly drawn; or

whether it be permitted to pass at will; whether the bowels move daily, or be purposely confined; you will have a successful result. There is more credit due him who has devised and popularized this preparatory treatment than to those who have suggested the suture, and the other advantages of operating. This preparatory treatment should be resorted to in nearly every instance, so as to remove every condition that may be detrimental to success.

We find in vesico-vaginal fistule, that the vagina and vulva are often in an inflamed and excoriated condition; that there are often phosphatic deposits within the vagina and upon the vulva; and if the fistulous opening is large the mucous membrane of the bladder may protrude in an unhealthy condition; that frequently the vaginal walls are indurated, and bear cicatricial bands, causing great contraction. Now, if the operation be performed while these conditions exist, it will almost invariably result in a failure, while if, by the preparatory treatment, the vagina be brought into a healthy condition, success will usually follow. It should be thoroughly washed out twice daily, with hot water, and all the phosphatic deposits which may have accumulated cleared away. Should the warm water fail to accomplish this we should touch each deposit with a weak solution of nitrate of silver; should the mucous membrane of the bladder protrude into the vagina in an inflamed condition, it may also, occasionally, receive the same application. Following this, the excoriated parts should be regularly anointed with some soothing unguent, to protect the raw surfaces from the irritation of the urine which is constantly dribbling over them. We usually, in these cases, find the urine phosphatic, and this condition may be best remedied by the administration of benzoic acid and borate of soda in doses sufficiently large to accomplish the purpose; the dose may then be diminished to such an amount as will keep the urine acid.

If there be cicatricial bands in the vagina they must be removed by nipping them with a pair of blunt pointed scissors, using the finger as a guide, care being taken not to cut through into Douglas' *cul-de-sac* posteriorly, nor into the bladder anteriorly. This process may cause profuse hemorrhage, but this can be controlled by the ordinary hæmostatics, or by the introduction of Sims' vaginal dilator, which must not be too tight, lest it cause injury by cutting off the circulation, and the consequent production of a slough. It may be held in position by a T bandage, and should not be removed until the parts around it begin to suppurate, and then the vagina should be washed out, once or twice a day, with carbolized hot water. In the course of a week the wounds will have healed, and the parts will then generally be in a soft, healthy condition. However, if bands are still left, we should continue to divide them until the vagina is in a healthy condition. When this is accomplished, we are prepared to operate with good assurances of success. We will find that the edges of the fistule can then be brought together and easily coaptated, and, when united, they will hold together without any difficulty. If we operate without this preparatory treatment, we must bring together diseased cicatricial tissues, which are inelastic and continually maintain the parts upon the stretch, and frequently tear the parts asunder. These cicatricial bands having been removed, the edges of the fistule will readily come together, unless it be a fistulous opening that has been attended with an immense deal of sloughing of the septum.

The patient now being prepared, her bowels should first be moved by some gentle cathartic, and just before the operation, by an enema. Although it is customary to give chloroform, yet we can operate upon many cases by administering simply a full dose of opium or morphine long enough before the operation to have its full effects induced. In this country the patient is generally placed upon the left side, in what is known as Sims' position. Prof. Simon operates with the patient in the exaggerated lithotomy position; Bozeman in the knee-elbow position. We generally use Sims' speculum, or some modification of it; Bozeman uses a self-retaining speculum which he himself devised. Select, however, that which suits your purpose best, and you will probably prefer some form of Sims'. Three assistants will be necessary; four if we give an anæsthetic.

Now, with the parts thoroughly exposed, we catch the mucous membrane on the edges of the fistule with a tenaculum, and with the knife, or variously curved scissors, begin denuding the surface. By a little pains and some dexterity we will find ourselves able to take out the mucous membrane all around the openings in one continuous piece. This denudation should be carried out nearly half an inch upon the vaginal tissue, and should come down only to the mucous membrane of the bladder. Prof. Simon cuts deeply into the cystic mucous membrane, but there seems to be no necessity for invading this tissue, and, besides, when we do so, there is danger of profuse hemorrhage, one or two instances being on

record where such practice has been followed by a fatal result from this cause. The late Dr. Peaslee, of New York, recorded one such case. The edges being now thoroughly denuded, the sutures are introduced, and they are brought together. These should be, if possible, introduced so that the resultant cicatrix will extend in a longitudinal direction, in order not to shorten the vaginal wall, and thus displace the uterus: They should be introduced half an inch away from the denuded surface and carried down and out, just at the cystic mucous membrane, bringing them out at a corresponding distance on the opposite side; a distance of an eighth to a fourth of an inch apart will enable us to bring the edges perfectly together.

After the hemorrhage has all ceased, each suture, being drawn sufficiently tight, should be twisted and cut off, leaving about half an inch, which should then be doubled down upon itself. This being done, with a probe we should press down on every point between the sutures, to determine if any part be imperfectly coaptated. In order to determine this more accurately, we may inject the bladder or the rectum with colored water, when, if any be passed into the vagina, an additional suture must be introduced at that point where the opening appears.

The operation being completed, place your patient in bed, and introduce a self-retaining catheter, either Sims' sigmoid or Skene's modification of Goodman's, the latter of which I prefer. With this in position the patient may get up and walk about at any time after the operation. Permit the bowels to move daily, neither purging nor allowing constipation to exist. Give good, nourishing, and easily digested diet, not stimulating diet, and if called for, opiates, to relieve pain. After the tenth day remove the sutures, being careful and gentle, otherwise you may separate the union that has occurred. Let the patient continue to wear the catheter for a week after the sutures have been removed. It should be frequently examined and kept open and clean. Should any part be found ununited it should be touched with some stimulating application, which may probably cause it to unite, if not too large.

The importance of this preparatory treatment is also well illustrated in those cases where the parts are kept clean and in a healthy condition. Where, in chronic cystitis, an artificial vesico-vaginal fistule is made, to cure the disease, often, in spite of our efforts to keep the fistule open, it unites.

The great difficulty after an opening made by an incising instrument is to prevent a union of the edges if the parts are kept clean.

For this reason the method of operating for bringing about artificial vesico-vaginal fistule is by the galvano-cautery. This tendency of artificial fistule to close should encourage u , in those cases that come immediately under our control after injury in labor, to resort to appropriate treatment with the hope of bringing about union by granulation. We should use a self-retaining catheter, and have the vagina washed out daily, and keep the parts perfectly free from any phosphatic deposits by applying a weak solution of nitrate of silver from day to day. If we fail to effect a permanent cure in this way, we certainly lessen the magnitude of the opening, relieve a great deal of suffering that would otherwise have to be endured, and bring about a condition that will facilitate any operation that may subsequently be undertaken for the removal of the difficulty.

Communications.

PNEUMONIA.

BY HIRAM CORSON, M.D.,
Of Conshohocken, Pa.

(*Continued from p.* 60).

I have been in active practice continuously for fifty-two years, and during all that time have not once had occasion to believe that there was any change in the human system, or in the climate, which made it more hazardous to treat acute inflammatory affections by means of cups or leeches, and other anti-febrile remedies, than it was in the beginning of my career. I am, therefore, free to declare that it is just as safe to use them now, and they are quite as efficient, as they were in the days when the physicians of Philadelphia were using them so freely, with so much confidence and with so great success. Surgeons now perform fearful operations, by which not only is a great amount of blood lost, but the patient is also injuriously affected by the shock to the nervous system, and yet the recoveries are oftentimes astonishingly rapid. Women, in time of childbirth, often flood until they are in the very presence of death, and yet, when it is arrested, they will, in a few days, be found as bright and cheerful as if nothing had happened ; soon regain their usual strength, and have no disability from their loss of blood. They bear it as well now as they did fifty years ago. Even those who would not bleed a woman in labor to save her from convulsions, have no fear that she will suffer

from a flooding which happened after the delivery of the placenta. A man may cut his leg and bleed till he faints, but no one feels that the mere loss of blood will do him any permanent injury; and yet what a hue and cry from these same people if a physician should bleed a person to remove a congestion of brain, or relieve a pain in the head or a pleurisy. I have rarely met with a graduate of the last fifteen years who has ever used a lancet, and yet these are the very persons who are so opposed to its use. They regard the older physicians who do use it as persons who are ignorant of the "valuable new remedies," (which they believe were discovered about the time they began to study medicine), when the truth is they are themselves ignorant of nearly all the means of cure, save veratrum viride, aconite, digitalis, a few cathartics, morphine, chloral, and—I was near forgetting them—poultices; poultices for croup; poultices for diphtheria and scarlet fever; poultices for the liver and poultices for the kidneys; poultices for the chest and poultices for the belly; and when you ask them what effect they expect from these means, they have no answer but this, "they are very much used in the hospitals now." Is there any reason why physicians who practiced forty years ago should not know as much of all the above remedies as these men educated during the crusade against blood-letting? Digitalis was much used long since; forty years ago I used tincture aconite, with good effect in many cases, as did others who then practiced; and as for newer remedies, does any one suppose that such men as Dr. John Atlee, Dr. Traill Green, Professor Gross, and hosts of others—practitioners and close students—are ignorant of the reputed merits of these champion medicines.

But I must submit some proof that blood-letting is well borne and very useful in pneumonia—as useful indeed as in times past, when it was considered of first importance.

During the Fall of 1880 ague prevailed along the Schuylkill River more than for years before. On the 26th of November I was asked, while attending another person, to see Wm. Canarra, a stout young man of 20 years, who two years before had contracted ague in Kansas, and who had returned somewhat broken in health, but for the last eighteen months had been well and strong. On seeing him, he told me that he had had a very severe chill a few hours before, that then he was laboring under a fearful headache, high fever, great thirst, and could get no rest. Without any examination of him, supposing that he had had an ague chill, I ordered some quinine, some morphia, to relieve his restlessness and headache, and left him.

I did not see him next day (27th) till afternoon; his head was relieved, he had rested better, but was feeling badly; had some pain and soreness in the right side of the chest, had coughed somewhat, and in a basin by the bed there was a very little sputa, slightly rust-colored. Then I did what I was most reprehensible for not having done when I first saw him, namely, examine him properly. I found congestion of a great portion of the left lung and an almost entire absence of respiration. I prepared to bleed him, but he objected, on account of his *great weakness*, and here is a proper place to call attention to this characteristic of pneumonia—the *feeling of prostration*, the *sense of great weakness*, which invariably attends every grave case, and which, by the opponents of blood-letting, is deemed a clear and pressing indication for stimulants and nutritious food. I bled him about ten ounces, when he was seized with a cough and threw himself suddenly around on his side, to expectorate, twisting his arm so as to arrest almost entirely the flow of blood; then he complained of being sick, a ruse, I think, to get me to stop it entirely. I knew he was not sick from loss of blood, for the pulse gave no indication of it, but I loosed the bandage, gave him nine grains of calomel—don't be frightened—to be followed by oil, ¼ gr. morph., to allay pain, and left him for the night, without a nurse save his old grandfather.

Sunday, 28th. On visiting him I was startled by the appearance of the expectoration. The whole bottom and parts of the sides of a large white wash-basin were covered with a glairy mucus, mixed with some bright red blood and much rust-colored sputa—or, as it is sometimes called, "stewed-prunes expectoration." He had the heavy, dull flush of pneumonia, and the affection had spread over almost the entire left lung. Here was a patient before me whose disease, owing partly to my negligence, had progressed for two days without check. The little that I had done was mere trifling. I was ashamed of my work, and the question arose, in the presence of his great weakness, and of the great extent of affected lung, "have I delayed my depleting remedies too long?" Shall I now resort to them, when his lung is so heavily congested, and suffering from inflammatory engorgement? When the atmospheric air has but one lung to act upon to vivify his blood, shall I depress him still further; reduce his strength and unfit him for bearing up against the great weakness which will surely come on if the disease advance to the third stage?

I could not go out and call to my aid eminent professors who could tell me whether it was catarrhal pneumonia or croupous pneumonia, and who could assure me, warn me, indeed, that remedies which would be safe in the one disease would be fatal in the other; so I was forced to answer the questions myself. I said, two days ago this youth was well and strong, but from some cause an irritation has set up in a small part of his lung, which, like a thorn in a man's hand, has invited a flow of blood to the part. As the irritation extended, congestion followed and aided to further spread and intensify it, until now we have an inflammatory engorgement of a great part of the left lung. The primary irritation and congestion caused a chill, soon followed by increased heat, frequency of pulse, headache and great disturbance of the whole system. He has nausea, even vomiting, restlessness and a feeling of great weakness—so great, indeed, that the believers in blood poison would attribute all those symptoms, all his sufferings, to that unknown something which had insiduously made its way into his blood, perhaps months ago, and was waiting ever since for a bad cold, or some over exertion, or a sleep of a night in the cold bed of the "spare room," to help it to attack him successfully, and is now threatening his life by perverting the secretions of all his vital organs.

Although the lung is seriously affected, so greatly, indeed, that the viscous fluid and blood, some bright red and some rust colored, are being forced out of the lung by the distention of its blood vessels, they are not concerned about *its* condition, "for, as the disease cannot be cut short, will run its prescribed course of a certain number of days, and go through its three stages, we will," say they, "let it alone, and turn our attention to the liver and kidneys, which are draining the blood of its strength-giving ingredients." And then, to save the patient, they will send some remedy to correct the action of the kidney, something to do battle with the poison, and something else to look after the liver. Although there is great nausea and occasional vomiting, they, regardless of its condition, regardless of the aversion of the patient to every kind of food and drink, save that of cold water, which is most earnestly craved, refuse him the latter, and *force*—the word is not too strong—him to take food, in most immoderate quantities, to supply a waste which they believe is going on from kidneys and liver. Why, a learned teacher told the students, this winter, that he had really known albumen to be discovered in the urine of a patient, ill with pneumonia. What an alarming fact! That will go into five hundred "note books." I have no belief in their theories, none in their practice.

But I have forgotten my poor patient. Poor, did I say? poor in what! Only poor in money. If I can stop the pneumonia and restore him to health, what wonderful possibilities may be his! Grant and Lincoln and Garfield were once as he is now—depending for daily bread on daily work. And now, my good boy, neither the timidity of advanced age nor the false teachings of the present days shall stay my hand, nerved to strike for your safety. There is no poison in your blood; the inflammation of your lung produces all your sufferings—your great heat and thirst, your nausea, headache, and hurried and oppressed breathing; while there is congestion, inflammation, even consolidation, there is no disorganization of your lung, and if I can arrest further extension of the inflammation by moderating the flow of blood there, and especially by relieving the blood vessels and capillaries of their fullness and distention, I shall not only arrest, but also moderate the inflammation, and then Nature will do the rest, namely, rid these small vessels of their half-stagnant blood, which press upon the small bronchioles and shut out the air. Having thus communed with myself, and remembering that I had often seen patients prostrate from excessive congestion of the lung made strong by the loss of blood taken from the arm, I bled him, as he lay there, sixteen ounces; then turned him on his side and applied two light tumblers to his back, and took four or five ounces more. Prior to these operations his pulse was 120; respirations, 42; temperature in axilla of sound side, 104°. Over the fore part of the chest I then applied cantharidal collodion freely—not cold water, or a bladder of ice and water, as I would, perhaps, have done if there had been a nurse to be always with him. As he had not been moved by the calomel, I ordered ℥j castor oil every three hours till the bowels should be well moved; then to have one-fourth of a grain of sulphate morphia, to be followed by a sixteenth, every three hours, if needed to suppress cough; cold water to be given whenever he asked for it, and as much of it as he could drink. Pretty sharp treatment, this, for a man who. in the hands of some of my Philadelphia friends, for whom I have the greatest respect, would have been considered so weak, from blood poisoning, that whisky, and quinine, and muriate and carbonate of ammonia, and beef tea, and other supporting things, would be needed. I saw him again at 4 P.M., seven

hours after the morning visit; respirations 40, but not labored, pulse 104, temperature 103°. He expressed himself as being much relieved. The blood drawn at the former visit was still in the bowl in which I had drawn most of it. There was a firm clot floating in the serum, with a firm, "buffy" coat covering its top. I took hold of this by a very small pinch of the ends of my fore-finger and thumb, and held it above the bowl by that alone. Did this indicate that the blood had been drawn from a person who was suffering from great weakness caused by blood-poisoning? I do not believe any man living has ever seen that firm, strong, buffy coat, come on the top of a clot of blood drawn from a man in whom there was not, at the time present an acute inflammation, or a state of robust health, or of morbid excitement of the arterial system caused by excessive stimulation. Well, this is only my opinion. Dr. Weir Mitchell, perhaps, knows more about the physical properties of poisoned blood. Until this time he had not had a regular nurse; his nights and a great part of his days were spent alone; but the nurse had arrived and I left him with her. When I saw him next day, at 10 o'clock, he had been well purged, and I found him greatly improved in his feelings, breathing only thirty times per minute and appearing very comfortable. There was, too, only a very little of the characteristic sputa in the basin. I was delighted to see how greatly he was improved, but did not visit him again that day. On the next day, the moment my eyes rested on him I knew he was worse. He had fever, said he had had a slight chill in the night, and again the basin had an increased amount of blood and rust-colored sputa, glairy and tenacious, so that the basin might have been inverted without its falling out. It was evident to me that the inflammation had been lighted up again, possibly by his rising. Dr. Pepper thinks there is danger in doing so. I bled him again, twelve ounces, when a slight nausea came over him and a warm perspiration covered his hands and arms, and I felt that I had gone far enough. I knew then that I was master of the situation. From that time I had no more trouble with him. I kept his bowels regular, suppressed his cough, when necessary, by small doses of morphia, gave milk as food—and nothing but milk—and from day to day could mark the gradual relief of the lung, the air gradually gaining access to new portions of it, from which for some days it had been almost wholly excluded.

I quote now from my notes of the case. To-day, December 5th, I find him happy and comfortable; a medical student in his third course of lectures, whose ears are better than mine, and who had seen him with me a few hours after I had cupped and bled him, in the very height of his difficulty, says that he can faintly hear, in almost every breath, the air in almost every part of the lung, the moist râles varying in proportion to the amount of obstruction. Mark, now, that during all this time he has had, as food, only milk—and for the first few days not a drop of even that—only water—iced-water when he could get it. In the early part of this disease—at least in grave cases—as well as in scarlet fever, diphtheria, and generally in fevers, the stomach loathes food, and I believe it is a real injury to the patient to have it forced on him. After the first four or five days this loathing of food is not present, and patients can generally take it with comfort and advantage. As soon as I have subdued the inflammation I allow nature to do the rest of the work. I care but little for the kidneys or the liver, knowing full well that, now, when the local irritation has subsided, and the heart is resuming its ordinary regular work, they too will return to their accustomed duties, from which they had been drawn by their sympathy with their neighbor, the lung, in his great distress.

The above was a badly managed case in the beginning, and I am not proud of it. If I had done my duty on the first and second days, he would have been quite well in a week. However, he is as well and hearty now as any one, and the case serves well to show that bleeding may be freely practiced in quite an advanced second stage of active inflammatory engorgement, with safety and good advantage. If agreeable to you and your readers, I shall be gratified to have an opportunity to give a few more cases to show the value of blood-letting.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

A CLINICAL LECTURE BY WM. PEPPER, M.D.,
Professor of Clinical Medicine in the University of Pennsylvania.

REPORTED BY WILLIAM H. MORRISON, M.D.

Catarrhal Phthisis, Tuberculosis of the Lungs, Tubercular Ulceration of the Intestines.

GENTLEMEN:—I bring before you to-day the specimens from a case, the history of which is of a very interesting character; so much so that I shall beg your careful attention to the history and symptoms before turning to examine the specimens.

The patient was a young man, about twenty-three years old, the eldest of a family of twelve, living in a healthy district of country. At the age of fourteen he took charge of a responsible position, and wore himself down. He was never very vigorous, and about the early part of last year he was on a midnight sleighing party and took a heavy cold, which undoubtedly resulted in a pneumonia. He was very sick for a few days. Then he got about again and continued to have cough, but not much expectoration; some failure of flesh and strength; but he still went on with his business.

When I say he had a pneumonia, I do not mean that he had a severe attack of croupous pneumonia, but probably a slight attack, a catarrhal pneumonia. The cough became less and less marked; but he then began to be troubled with diarrhœa, which continued more or less until the close of his life. Again, he paid very little attention to the diarrhœa, ate about what he pleased, and kept about his business. He took a good deal of patent medicine, and went to a number of places, but with little relief.

I saw him first on the 1st day of May, seventeen days ago. He reached this city with great difficulty; the journey was almost too much for him. I learned that it was thought that he had not had much fever, no cough nor expectoration; that his lungs were regarded as sound, and if he could go to the seashore, take plenty of oysters, and so on, he would come around all right.

His appearance was horrible; he was emaciated to the last extremity. When I saw him his pulse was rather slow, and the temperature about 98°; this was in the morning, about noon. When I saw him next day and made a careful examination, I found that it was one of those unusual cases of very extensive disease with very few general symptoms. Physical exploration is, in such cases, the only means of determining the condition present, but in some such cases, because of the debility of the patient, and the fact that, owing to the flux from the intestinal canal, the amount of secretion from the lung is small, there is often little cough and expectoration, and the physical signs are obscure and only developed with difficulty.

The physical examination showed that there was no extensive dulness at any part, and the respiratory movement was everywhere impaired. The chest was long, shallow, poorly developed, of the phthisical form. At some places, however, after making the patient cough—and in such cases, where the movement of the chest is impaired and the respiratory murmur feeble, you will, if you make the patient cough, develop sounds that you could not hear before—I heard unmistakably, soft râles, such râles as indicate softening of an exudation in the alveoli of the lung. It was clear that there were scattered seats of disease in the lung; at no place had they run together, forming large masses, and at no place did they form a cavity.

I think that in these cases the lung tissue around the diseased part becomes emphysematous, and thus tends to cover up the dulness. Now these obscure physical signs are met with in certain cases of chronic catarrhal phthisis, where there is not much expectoration, and particularly where there is associated intestinal disease, because in this the amount of fluid in the air passages, which you know gives rise to many of the physical signs, is much diminished.

Secondly, I learned that the stools varied in number from one to a dozen in the twenty-four hours; in color from yellow to greenish or blackish, sometimes containing specks of blood and sometimes little patches of mucus; that there was a good many cutting pains through the belly, that these alternations of diarrhœa, from worse to better and from better to worse, seemed to be produced by changes of weather and indiscretion in diet.

There was no thickening, that I could find, of the intestinal walls, at any point. The abdomen was a little distended and a little boggy on pressure, but the great emaciation everywhere else made the prominence of the abdomen more marked. I formed the opinion that there was extensive ulceration of the bowels, secondary to the lung disease. that it was probably associated with enlargement of the mesenteric glands, and quite possibly with subacute peritonitis.

I was surprised to learn the next day that there had been an extraordinary change of temperature. The variation of temperature in this case the day after he came in, was from 97° or 96° in the morning, to 102.5° at night. Six days after this came another and most extraordinary range of temperature, from 96° in the morning, to 104.5° at night, followed by a fall the next morning to 96.8°. This temperature movement is more remarkable because, as you see, its great range is caused by going below normal, showing a marked condition of mal-assimilation and poor calorifacient power, causing the cold stage to be attended with a very marked reduction of temperature, so that the intense fever only carried the temperature up to 102°, 103° and only in one instance to 104°; the daily range being from 6.5° to 8.5°.

When I found this young man with his skin cool, his pulse seventy-eight per minute, and his mind clear, it gave me a favorable opinion of his case. But when I noted this terrific hectic fever, I recognized that here there must be a most enormous amount of inflammatory disease, of an irritative or destructive type, to keep up such a state.

The course of the case was rapidly downward. The diarrhœa was controlled by the use of a very carefully restricted diet, the avoidance of all remedies by the mouth and the use of injections of nitrate of silver and opium; so that soon he passed but one stool a day. Under this treatment his tongue, which had been aphthous and raw, cleared off somewhat, his stomach became a little easier, and with this improvement you will observe that the range of temperature became a little less extreme, but none the less did the downward course continue. He soon became delirious and died last night.

Let us first examine the lungs. The right lung is more extensively diseased than I had imagined. I knew that it was riddled, but I did not expect to find such marked changes. There are no large cavities, but here are two or three small ones, about half an inch in diameter. The upper lobe of the right lung is riddled with gray

tubercles. Unquestionably a true tuberculous formation has taken place secondary to the old pneumonic process, and traces of the pneumonic process are found in the upper part of the lung, where softening has occurred, and this tubercular infiltration is all through the upper lobe. The lower lobe is congested and œdematous, but presents few, indeed, I think, scarcely any points of disease.

Upon the left side I find the upper lobe very extensively involved, and in just the same way as on the right side, except that here the lesions are more recent. They consist of infiltration with grayish and yellowish-gray miliary bodies, not sufficient, indeed, to cause complete solidification, but little blocks of solidification are found; between which are areas of crepitant tissue. There are a few cavities. The lower lobe presents a few scattered nodules of disease.

We have, then, extensive lesions in both upper lobes, originating in a pneumonia, and now the development of true miliary tubercles, while the lower lobes remain comparatively healthy. Think how remarkable it is that this man was said to have no organic disease, but at the same time remember the peculiar circumstances; for the man's power of filling his lungs was so weak that nothing was audible over his lungs, and it was only when I made him cough, thus causing him to take a deep inspiration, that I could develop any râles.

I shall now take up the other organs as I have them.

The kidneys are normal. The urine was normal.

The spleen is very much enlarged. About twice its natural size. Its structure appears to be normal.

The liver is normal in size, color and weight. I always speak with diffidence in regard to the presence of tubercles in these organs, because minute miliary tubercles may exist and only be discovered by the microscope.

I turn now to study the intestinal canal. The stomach presented no evidence of disease, and it is not necessary to open it. I see at once enormous enlargement of the mesenteric glands. I am now at the termination of the ilium, in the ileo-cæcal valve. This enlargement is probably most marked in the middle of the ilium, but it extends far up towards the duodenum. Now I shall ask you to note further the characteristics of this enlargement. We see, in the first place, that the glands are of a grayish-yellow color, not pink or red. I dwell upon this because I want to call attention to the difference between this enlargement and that which takes place in typhoid fever, when we consider the condition of the intestinal mucous membrane in relation to that of typhoid fever.

The enlargements vary in size from a small pea to a large almond. On section they present a pink and a yellowish periphery. In typhoid fever the gland is softer and throughout reddish or pinkish. This ulceration is different, because the gland has evidently undergone cheesy degeneration. Fatty change has shown itself here, just as it has in the lungs.

Although it is true that the mesenteric glands are enlarged, they are not more enlarged at the ileo-cæcal valve than they are higher up, in fact, they are scarcely as large as they are higher up. In typhoid fever, as you know, it is the glands about the ileo-cæcal valve that are by far the most enlarged, and as we go along the ilium, we find the enlargement grows less as we pass upward. Chronic enlargement of the mesenteric glands is often found in old cases of ulcer of the bowel. My judgment is that there are plenty of true tubercles in these glands. Their enlargement is common in all forms of ulceration of the bowel, particularly when the ulceration is of a tubercular character. It would seem that these glands had undergone irritative hyperplasia, and that in various places had been formed tuberculous nodules.

Now, as I expected, I find tubercular peritonitis also present. The peritoneum is purplish and congested, and scattered over it are scores of miliary tubercles. This is most marked towards the cæcum. I find also numerous yellowish granulations.

Lastly, let us see the condition of the mucous membrane. In opening the bowel, whether the ulceration be typhoid or not, it should be opened at the insertion of the mesentery, not opposite to it, because it is important that we should be able to observe the relation of the ulcer to the glands of Peyer, and these lie at the convexity of the arch. I shall only open a couple of feet of the intestine, extending the incision for a short distance into the cæcum. The only basis of sound practice of medicine and of sound diagnosis is morbid anatomy. I always take every opportunity that presents itself, to impress on your minds not only the appearances, but to associate them with the symptoms.

I have now opened and washed the bowels, and you see, there is scarcely a particle of mucous membrane left. Serpiginous ulcers, which defy localization, extend everywhere. This is not at all the appearance of ulceration of Peyer's patches. The latter are oval in shape, seated in the middle of the bowel when it is opened as I have directed, with their long axis corresponding to the long axis of the intestine, surrounded by a raised lip, and between them perfectly healthy mucous membrane, with enlarged solitary glands, which may or may not be ulcerated. I find here about an inch of mucous membrane in which there is an oval ulcer, but its long axis is transverse. If it were a typhoid ulcer its axis would be longitudinal. When we come to the ileo-cæcal valve, there is no mucous membrane for several inches. The condition is just as bad in the large bowel as in the small. There are the lesions of chronic dysentery, chronic ulcerative entero-colitis. These are just the kind of lesions that are met with in old cases of chronic dysentery. Are there any miliary tubercles in the intestine? That can only be told by a microscopical examination, but I think there are.

We have, then, in this case, the most advanced and intense lesions of tuberculosis of the lungs and of the intestinal canal, originating in a pneumonia of one or both lungs, unnoticed and improperly treated, not cured, grafted on a system exhausted by premature and excessively hard work, but with no tuberculous tendency.

This is an acquired condition, for he was one of a family of twelve children; the grandparents and the rest of the family were vigorous and well, living in a perfectly healthy district. The inflammation went on to cheesy degeneration, infection of the system and the development of tubercles in both lungs and the intestinal mucous membrane, and lastly, secondary deposits in the peritoneum, and secondary involvement of the mesenteric glands.

Galloping Consumption.

Here is a patient suffering from this same process of infective tuberculosis. He has been barely able to get here to-day.

John Gallagher, not quite seventeen years old, a delicate lad. He has been engaged in measuring grain from 5.30 A.M. until 9 or 10 P.M. One sister died at the age of fifteen years and six months, and another at the age of eighteen years. Both of phthisis. The first died after nine months' sickness, the second after six months. His mother died of cancer of the axilla. His father and one brother are living.

With this hereditary tendency, he is put to work in a close, dusty atmosphere, working sixteen or seventeen hours out of the twenty-four, for the last four years. It is hardly necessary to say what the inevitable result has been. He took cold, that is, his system became so exhausted, his nutrition so impaired, that finally some change in the weather, or something of that kind was sufficient to set on foot the inflammatory process. The expectoration became profuse, the night-sweats have been continuous. Dyspnœa has been a marked symptom from the first. His features are drawn and pointed, eyes sunken and hollow, the respiration exceedingly rapid, the surface bathed with sweat and the pulse very rapid, 160 per minute. This, probably, indicates the height of a paroxysm of hectic fever, which often has its maximum about two or three o'clock. His temperature is 102 5°.

On auscultation I hear innumerable fine crepitant râles on inspiration and expiration, at the left apex, some at the mammary region, less numerous but distinct at the sub-axillary space, less marked but quite distinct posteriorly.

Observe, that with this complete infarction of the whole lung with miliary tubercle, for there is not one-eighth of a cubic inch that has not got plenty of them, there will be, I think, as there is generally, so much dilatation of the vesicular structure as to prevent any considerable degree of dullness. This is not vesicular resonance, but vesiculo-tympanitic. On the right side I find a large cavity. Here has been, I suppose, the origin of the disease, a pneumonic inflammation of the right upper lobe. Here we have cavernous respiration, with gurgling râles, as though one was blowing soap bubbles. The blowing breathing is distinctly heard over the scapular region, showing that the cavity is deep and surrounded by solidified lung tissue.

Percussion at the right apex gives a tympanitic note, and an extremely marked cracked-pot sound. We have here a large cavity with thin walls anteriorly. Below the solidification is great enough to give considerable dullness.

The bowels are open sometimes two or three times a day. They contain no blood, but are thin. There is no pain in the belly. He never spat up blood until last Sunday. The tongue is pale, coated and tremulous, as he is all over. (The patient being sent from the room, Dr. Pepper continued.)

Here is a horrible illustration of the rapid progress of true tubercular disease, being, as it so often is, induced by some previous malnutrition or exposure of a system inclined by hereditary tendencies to cachectic disease. It is no wonder, then, that this lad, exposed at an immature age to excessive over exertion, in an atmosphere filled with irritating particles of dust, should become so rapidly run down with disease. I have no doubt but that he also has ulceration of the bowels, and if the disease was not making such rapid progress, we would have the lesions which we saw in the other case; but he will probably be dead in the course of two weeks. This is a case of galloping consumption, so called.

Medical Societies.

NEW YORK STATE MEDICAL SOCIETY. ANNUAL MEETING.

The Society met at Albany, February 1st, about one hundred and twenty-five members being present, in spite of the excessive severity of the weather. During the session a daily report of the proceedings was published by the Medical Society of the County of Albany, in the form of a daily edition of the *Medical Annals*. We are indebted to this for most of the report which we furnish.

The President, Dr. Wm. H. Bailey, of Albany, called the Society to order at 11 o'clock A.M., and read the opening address, chiefly devoted to the consideration of the social and legal relations of the profession and to the necrology of the Society.

Passing over the business matters which occupied the session, the following scientific papers were among those read:—

Dr. David Webster, of New York, read a paper on

SYMPATHETIC NEURO-RETINITIS.

After a careful consideration of seven cases of this affection mentioned by Von Graefe, Stettburg, Schweigger, Alt and Pooley, and two cases reported by himself, Dr. Webster is of the opinion that the question of the sympathetic character of this disease still remains an open one.

Dr. Norman L. Snow, of Albany, read a paper on

LITHOTRIPSY, WITH ENTIRE REMOVAL OF FRAGMENTS AT SAME SITTING, BY BIGELOW'S ASPIRATOR.

After an interesting review of the history of the operation, the Doctor reported the following case:—

Robert A., an American by birth; age fifty-three; family history good; first noticed trouble in micturition in spring of 1879. In November of same year chronic cystitis was diagnosed, and treatment therefor instituted during the fol-

lowing winter. In October, 1880, was examined with Thompson's short curved sound, and a small stone detected, which rapidly increased in size until December, when the operation was performed. The entire time occupied in the operation was thirty minutes; weight of fragments eighty grains. On January 6th, ten days after the operation, he was able to attend to business.

Dr. Charles A Bull, of New York, then read a paper on the

PATHOLOGY OF ORBITAL TUMORS, INVOLVING THE BONES OF THE ORBIT.

He attributes the recurrence of these growths to the cellular elements left in the shreds of orbital tissue, or in the many fissures and sinuses communicating with the cavity of the orbit, or that the periosteum or bone may have been the primary seat of the disease. He classifies these tumors as pure sarcoma, myo-sarcoma, or fibro-sarcoma. The secondary processes observed in bone and periosteum are a general infiltration, softening and degeneration of bone tissue, and the development of exostoses, osteophytes, from and in the walls of the orbit. The influence of locality upon the development of sarcomata is clearly evident. The osteo sarcomata appearing on the surface of bones and the softer forms in the medullary cavities. But in the orbit, the tumors are mostly of the medullary variety. In removing primary intra-orbital sarcoma, careful search should be made through the entire orbit for enlarged lymphatics or infiltrated glands. Three cases were reported, of operations for the removal of intra-orbital growths. From a study of these cases, Dr. Bull thinks that operative interference hastens the recurrence of the tumor, and that the stripping up and removal of periosteum hastens the return in the bone, even when the latter has been scraped at the time.

Dr. L. Duncan Bulkley, of New York city, then read a paper entitled

FAVUS AND ITS TREATMENT BY A NEW METHOD OF DEPILATION.

After detailing his experience with several methods which had proved unsatisfactory, he advised the preparation of sticks of various sizes, from one-quarter to three-quarters of an inch in diameter, and cut off in lengths of two or three inches.

The formula is as follows:—

℞.	Ceræ flavæ,	℥ iij	
	Laccæ in tabulis,	℥ iv	
	Resinæ,	℥ vj	
	Picis Burgundicæ,	℥ x	
	Gummi dammar,	℥ iss.	M.

By the use of these differently-sized sticks, they can be applied to affected surfaces of various sizes.

They melt at a comparatively low temperature, and yet are hard at that of the body. The hair should be cropped short over the part to be treated, and as the stick is applied, a slight rotary or twisting motion is given to it. After it has been applied for several minutes, it is removed by bending it over, and drawing the hairs in succession. The hairs thus left in the stick are burned off. The operation may have to be repeated.

Dr. A. Mathewson, of Brooklyn, reported a case of

TRANSPLANTATION IN A CASE OF COMPLETE EVERSION OF LEFT UPPER LID,

as the result of contraction from burns. The lid was freed by dissection, and transplantation performed of a piece of skin three inches by one and a half inches, without pedicle. The result was union throughout by first intention. The advantages of the operation were said to be the ease of execution, with greater surety of success than by the old methods with pedicle or sliding flaps.

Dr. Daniel Lewis, of N. Y. city, then read a paper on

DRESSING OF THE UMBILICAL CORD.

He advises that the cord should be cut *before* the ligature is applied, and thoroughly emptied of blood and serous contents, thereby reducing the amount of material to be sloughed off to the minimum. It is then tied and twisted sharply three or four times, which torsion so closes the umbilical vessels that hemorrhage is about impossible, in case the ligature should prove imperfect. A band of rubber adhesive plaster, two by eight inches, is then tighly applied over it and allowed to remain until the parts are thoroughly cicatrized. This device is believed to be sufficient to prevent any protruding navel or umbilical hernia.

Dr. L. E. Felton, of St. Lawrence, read a paper entitled

MEDICAL INDUCTION COILS.

The Doctor said: A cell is used of original and peculiar construction, and an interrupter, which will produce most rapid vibrations. The current is regulated by means of a sheet of copper, bent over the coil, the connection being completed by means of a movable bar, which will bring any desired length in contact.

When the edges are in contact, the current is induced in the cover, as offering less resistance than the patient; but as the bar is removed, and resistance increased, the current which flows through the patient is correspondingly increased.

Second Day—Februrary 2d.

Among the papers read on this day may be specified:—

Dr. J. S. Warren, of New York city, read an abstract of a paper entitled

HYSTERO-NEUROSIS OF PREGNANCY.

From a consideration of several hundred cases, he does not believe that there is any specific for this affection, but that each case requires its own special treatment. Vomiting is not always, nor even in most cases, sympathetic, but arises from nervous influences, or from changes in the thyroid, spleen, liver and kidneys.

Dr. H. G. Piffard, read a paper on

MEDICINAL ERUPTIONS.

He stated that until within a very few years hardly any drug, except arsenic and the diaphoretics, was credited with a direct action on the skin. Effects upon the healthy skin, following the ingestion of drugs, are rare, yet—on this

very account—important to be recorded for reference. Practitioners should know all the irregular and abnormal effects of remedial agents, lest a medicinal rash be mistaken for an idiopathic affection of the skin, and the unsuspected cause be permitted to remain in operation. Thus far, dermatology has mainly considered the symptomatology and pathology of cutaneous affections, springing from what might be termed natural, though frequently obscure causes. There is need of careful observation of a different class of cases: those which arise through the agency of means intended to combat disease, but which, in turn, may become the originators of morbid action. While in many cases these effects are unusual, and commonly explained as due to some idiosyncracy, it is none the less important that they should be recognized at the time of their occurrence, and their true cause.

Dr. George F. Shrady, of New York city, related a rare case of

CONGENITAL INTRA-PARIETAL HERNIA.

In which he was able to make a diagnosis before death. The patient was fifty-four years of age; suffered from strangulation; refused an operation, and died on the eleventh day. A drawing of the specimen was presented, showing a congenital inguino-scrotal hernia, connected with which was a diverticulum of peritoneum, forming a supplementary hernial sac, extending upward and outward between the external and internal oblique muscles as far as the anterior superior spine of the ilium.

Dr. E. V. Stoddard, chairman of

COMMITTEE ON HYGIENE,

reported the general summary of the work for the year. The subject for observation had been that of diphtheria. Careful investigations had been instituted as to its contagious character, with especial view to the relative influence of personal contact, infection by clothing, and unsanitary surroundings. Its contagious character being undoubted, the question of *quarantine* in the public schools, as well as the family, was urged by the committee, and will serve as the subject for the coming year.

Dr. Elisha Harris, one of the State Commissioners of Health and Secretary of the State board, called attention to the present widespread prevalence of diphtheria and the utility of the general observations and records of the medical profession relating to its causation and prevention. He urged the necessity of bringing under the best possible control the unguarded causes of the distribution of diphtheria. He explained the necessity of isolation of all who are convalescing. The State Board of Health find it a duty to investigate the causes and modes of distribution—its infective as well as local causes. He called attention to the necessity of physicians teaching and inducing the proper care in preventing the spread of this disease.

Dr. E. C. Seguin, of New York city, read a paper on

THE EARLY DIAGNOSIS OF SOME ORGANIC DISEASES OF THE NERVOUS SYSTEM.

In diagnosing posterior spinal sclerosis, the following symptoms were stated as characteristic of the first or pre-ataxic stage: the peculiar pains, the diminution of various reflexes and the paralyses of ocular muscles. The earliest characteristic symptoms of paralytic dementia are tremors or fibrillary contractions, especially in the tongue, facial and manual muscles; a tremulous, thick and vibratory speech; irregularity of the pupils, and dementia. Tumors located in the motor zone are *sometimes* capable of early recognition. Their symptoms are localized convulsions in peripheral muscles; equally localized paralysis of peripheral parts; neuro-retinitis or choked disk, and localized headache.

THE PRESIDENT'S ADDRESS.

The annual address was delivered by President Bailey, at the Assembly Chamber of the New Capitol, on the duties and opportunities of the medical profession.

(To be Continued.)

Editorial Department.

Periscope.

Treatment of Abscess of the Liver.

The *Medical Press and Circular* states that at the Academie de Médecine, in November, a discussion took place on the communication made by M. Rochard relative to the treatment of abscess of the liver by a large and direct incision, combined with the antiseptic method of Lister. M. Depaul commenced by relating a case which occurred on board a steamer when he was going out to Brazil, six years ago. A passenger was suffering from a liver affection for some time, and had come to France to consult different physicians and surgeons of more or less note, and who had expressed different opinions on the nature of his case and the treatment to be adopted. He was now returning home, little benefited by his voyage. Being called in consultation by the ship surgeon, M. Depaul, after a minute and careful examination, discovered fluctuation in the organ in question. Soon it became evident, by the increase of the tumor and the commencing redness of the skin, that the pus was making its way to the exterior. M. Depaul proposed to make a large incision down on the abscess, which was accepted, after some hesitation. Accordingly, he made an incision of an inch and three-quarters in length, which divided successively the skin and the subjacent tissues, exposing a thin layer, under which the pus could be distinctly seen. He made a simple puncture in the layer, which gave exit to more than half a pint of

fetid pus, mingled with hepatic *débris* and some bile. After the evacuation of the matter detersive injections were employed, and before the ship arrived at her destination the patient was in a fair way of recovery. M. Depaul terminated by reminding the meeting that the Lister dressing was not employed in this case. M. Rochard, advocate of the new method, replied that he had known twenty cases treated according to the old rules, and the twenty died; whereas, three in which the Lister treatment was employed recovered. Surgeons who used this latter method need not trouble themselves as to whether the peritoneum be adherent to the abdominal walls or not, and take no care to provoke it either.

How to Prevent Perineal Laceration.

Mr. Alex. Duke writes to the *Medical Press and Circular*, Nov. 24: The best preventive treatment of laceration which I have found (and which I dare not claim as original, as I presume it has been tried before, but which I see no mention of in the text-books of midwifery) is this: When I find the head fairly engaged in the pelvis, and advancing with each pain, I take my seat by the patient's bed, and having lubricated my left thumb or the two first fingers of my right hand, I introduce either into the vagina, and at the onset of a pain draw back the perineum firmly but gently toward the coccyx, relaxing the tension gradually as the pain lessens, till the next ensues, and so on till I can draw back the perineum with very slight effort. I thus tire out the muscular structures and produce sufficient relaxation for the head to pass. In most cases so treated the perineum is in no danger, but when the pubic arch is narrow, I take the additional precaution to foment the parts, and use an inunction of lard, and also allow the head while passing through the vulva to glide over my lubricating fingers, using them as a shoe-horn, so to speak, while I direct the head forward by pressure with my left hand below the coccyx or a finger in the rectum.

It has always seemed anomalous to me that the perineum should be expected to dilate on such a short notice, namely, the "process of extension," while (dilatation of) the os and cervix occupy such a considerable time, even with the additional help of Nature's hydrostatic dilator, viz., the bag of waters.

The drawing back of the perineum produces no additional pain, as it is done during a uterine contraction, and I feel sure if nurses were educated as to the proper way of dilating the perineum previous to its distention with the fœtal head, we should see less and hear less of lacerated perineum.

Physiological and Therapeutic Action of Benzoic Acid.

The *Lancet* states, that from his experiments Schulte has found that the introduction of benzoic acid into the stomach of warm and cold-blooded animals always causes irritation of the mucous membrane, extravasation, and hemorrhagic erosion, and that similar irritation is sometimes observed, even when benzoic acid or its salts have been introduced by injection under the skin, or into a vein. In the latter case the pulse and respiration are at first accelerated, and afterwards retarded. The blood-pressure is not influenced by slight injections, but is lowered by stronger ones, and the phenomena are independent of the vagus nerve. Whenever the dose amounts to more than two-thousandths of the body weight of the animal, toxic symptoms occur, followed by death. Salkowski has pointed out that when benzoic acid is given the urine commonly contains a substance which is capable of reducing sugar. This body is not soluble in ether, but it is soluble in alcoholized ether and acetic ether. It is very slightly soluble in water, and thus is distinguished from both benzoic acid and hippuric acid. The salt it forms with barium is insoluble in water, and contains both nitrogen and chlorine. Schulte has found that the appearance of this substance in the urine corresponds in time with the appearance of toxic symptoms. In the therapeutic use of benzoic acid and benzoate of soda for diphtheria, acute and subacute articular rheumatism, erysipelas, typhus, diabetes, nephritis, interstitial phthisis, peritonitis, etc., the reducing substance was never found in the urine after a small subcutaneous injection, but was found when a larger injection was given. The salt was found distinctly useful only in acute articular rheumatism and diphtheria.

Two Cases of Spinal Irritation.

The subjoined interesting cases are given in the Glasgow *Medical Journal*, January:—

Case 1.—The patient is a strong, robust-looking young woman, aged 25, and evidently hysterical. She was admitted to the hospital on the 15th of November. She made no mention of any affection of the spine, but complained of pain underneath both mammæ, and in the left iliac region. The pain under the left mamma had been present for about eighteen months, and was of a dull, aching nature; that on the right side was much more acute, and commenced suddenly in August last.

The thoracic and abdominal viscera seemed quite healthy, but on making firm pressure with the fingers along the spines of the vertebral column, two tender spots were discovered at different levels, corresponding very much to the points at which the spinal nerves issue, which supply the areas in which pain was complained of. The patient winced visibly when those points were pressed.

A tonic mixture containing strychnia and quinine was ordered, and on the 18th of November two large blisters were applied over the tender parts of the spine. This was followed by a certain degree of relief from the mammary and iliac pain, by no means, however, complete. On the 29th, therefore, the blisters were repeated, and on the 8th of December the patient left, quite relieved of her symptoms.

Case 2.—The patient is aged 22, and enjoys fairly good health, but for three months before admission to hospital, on the 27th of November, she suffered from pain about three inches below the left nipple; this was increased during inspiration; she had also a dry spasmodic cough without any expectoration, and exercise of any kind

rendered her breathless. After taking food, too, she complained of pain in the gastric region, and was troubled with sour eructations. Her appetite was good. Two years ago the menses were suppressed for three months, and during that time she had an attack of pain in her breast, as at present, but on the return of the menses the pain disappeared. There was no apparent disease of the stomach at the date of admission to the hospital, and the heart and lungs seemed also sound. On examining the spine, however, tenderness was detected from the sixth dorsal to the first lumbar vertebra, and chiefly on the left side of the spine. Of this condition the patient was quite unaware until examined. On the 10th of December she was wet-cupped over the upper portion of the tender part of the back, to 10 drs. The almost immediate result of this was the entire disappearance of the spasmodic cough and the stomach symptoms, but the mammary pain still continued. On the 16th of December the cupping was repeated over the lower portion of the tender part, with the result of removing the pain of the side.

Indigestion from Disordered Liver.

Dr. T. Lauder Brunton says, in the course of an article in the *British Medical Journal*, January 8th, 1881:—

"One cause of indigestion is disordered relation between the stomach and the liver. Usually, the bile does not enter the stomach, but remains in the duodenum and intestines, but when indigestible and irritating substances enter the stomach, the bile may flow into it, producing very unpleasant symptoms; not merely does it interfere with digestion, by precipitating pepsine, but the local irritation which it produces in the stomach itself, as well as its general effect upon the nerve centres after being absorbed into the blood, causes the patient to suffer from dullness and headache. In Dr. Beaumont's interesting experiments upon Alexis St. Martin, he notes, that where he introduced several muslin bags, containing various articles of diet, into the stomach, St. Martin, shortly after their introduction, began to complain of a sense of weight and distress at the scrobiculus cordis, slight vertigo, and dimness of vision. This continued to increase, and became quite severe, accompanied, at the latter part of the time, by slight pain in the forehead and through the eyes, and a sense of tightness or stiffness across the breast. His countenance had changed from a florid and healthy, to a sallow, sickly appearance during the experiment, and a soreness at the pit of the stomach continued, after the extraction of the bags, for eight or ten hours, and had not entirely subsided next morning. Morbid action of the inner (?) membranes was evident next day, with considerable erythema and aphthous appearance. Some of the bags were covered with a thick, mucous coat, tinged with yellow bile; and to the entrance of the bile into the stomach Dr. Beaumont ascribes the symptoms observed in St. Martin, as he had noticed them also in similar experiments. Here, it was apparently the irritation of the indigestible muslin bags which caused this bilious attack in St. Martin; but other indigestible substances will produce the like effect.

Nor is this the only disturbance in the relation between the liver and the alimentary canal which is of importance in the production of indigestion. I have mentioned the probable effect of vaso-motor alterations in the liver upon the vascularity of the stomach and intestines, and upon the solution and digestion of food within them. But there remains still another condition of great importance. The digestion of food is not entirely accomplished in the alimentary canal. In addition to what used to be called the primary digestion in the stomach and intestines, there is the secondary digestion, which appears to be of no less importance. Farinaceous foods are converted, in the intestinal canal, into grape sugar, but apparently only a small amount of this sugar reaches the general circulation unchanged. It first undergoes conversion into glycogen in the liver, and is thence passed out, as it is wanted, into the general circulation. The albuminous constitutents of the food are converted, in the alimentary canal, into soluble peptones, but, like the sugar, these also do not reach the general circulation unchanged. Excess of sugar in the systemic circulation is injurious, as we see in cases of diabetes, but excess of peptones appears to be still more injurious. The action of these bodies has been recently investigated by Professor Albertoni, of Genoa, and by Professor Ludwig and Dr. Schmidt-Mühlheim in Leipsic. Albertoni has found that peptones, when injected in the circulation, deprive the blood of its power of coagulation, at least in dogs and cats, and probably in all carnivorous animals. It has not the same power in sheep or rabbits, and probably has not the same action in herbivora as in carnivora. Ludwig and Schmidt-Mühlheim also observed the effect of peptones on the coagulability of the blood, and they have investigated their action upon the blood pressure. They found that when the peptones are injected into the veins the blood-pressure sinks considerably; and, if the quantity introduced be great, a soporose condition, convulsions, and death are produced. It is, therefore, evident that, unless there were some provision for the alteration of peptones before they enter the general circulation, we should be poisoned by the products of our own digestion. Ludwig and Schmidt-Mühlheim were unable to settle precisely where the peptones underwent transformation, most of them having apparently already disappeared from the portal blood before it reached the liver. Two other observers, Plosz and Görgyai, were led by their experiments to fix upon the liver as the place where peptones undergo transformation, and it seems not improbable that, to some extent, they are right. The liver, like the stomach, may be overworked, and both organs are liable to great functional disturbance from violent or depressing emotions.

On the Means for Dilating the Uterus.

Dr. Leopold Landau (Volkman's *Sammlung Klinischer Vorträge*, N. 187,) mentions, first, the use of various metrotomes constructed after the model of the lithotome caché, but of these he disapproves, on account of the dangers of their

cutting too much, of bleeding, and of subsequent stenosis. For similar reasons he objects to the use of such instruments as Sim's or Emmet's knives or scissors. To dilate the os internum by means of such blunt instruments as those of Sims, Ellinger, Tiemann, etc., requires, he maintains, that the patient be narcotized and considerable force used, while there are similar objections to their use as to that of cutting instruments. Sponge-tents favour infection, so that septicæmia following their use is not rare. It is impossible, also, to render them thoroughly antiseptic without unfitting them for their purpose. The use of an india-rubber covering to the tent, with a stream of water thrown into it, is cumbersome, and also does away with the advantage to be got from the removal of fluids from the surrounding tissues by the sponge. Tangle tents are not so liable to lead to infection as are the sponge tents, though occasionally, from decomposition of their gelatinous structure, they may cause it. They are, the author says, very uncertain and unequal in their action, and have not a very great dilating power, being sometimes retained constricted by the internal os, while above and below they may be dilated. Dr. Landau then goes on to recommend the use of tents made from the South American swamp plant, *Nyssa aquatica*, by Tiemann, of New York, and called tupelo-tents. These can be made of any size, and have a much greater dilating power than tangle-tents, while they require less than half the time. They exercise, too, the same dynamic effect on the uterus as do sponge-tents. They swell to a much greater size than tangle-tents, and are not attended by the risks of infection. After recommending strongly their use, the author proceeds to discuss at length the question of when dilatation of the cervix is indicated, and strongly disapproves of the forcible method of Fritsch, as also the incision method recommended by Schrœder.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The *Archives of Dermatology* begin the year in enlarged form and on superior paper. The contents are always of the best, and all specialists in that department — including syphilis—should subscribe to it ($4.00 per year. G. P. Putnam's Sons, New York).

——The January number of the Half-Yearly Compendium of Medical Science will be found a synopsis of all branches of medicine, American and Foreign. A full table of contents will be forwarded to any one on application. Inasmuch as no article in the Compendium appears in the Medical and Surgical Reporter, the two journals are eminently adapted to be taken together, and combine an unequaled amount of original and carefully selected reading matter. Published at the office of the Medical and Surgical Reporter.

——One of the recently published anatomical aids is the "Pictorial Manikin, or Movable Atlas of the Human Body," showing the position of the Internal Organs, by means of superposed colored plates." By Prof. G. J. Witkowski, M.D., of Paris, with an English translation of the text, by Robert Hunter Temple, M.D., of London, and an Introductory Essay and Explanatory Anatomical Index, by Prof. D. A. Loomis, M.D., of New York. (Published by Joseph Cristadoro, 93 William street, New York. Price $5.00). We have long been familiar with this method of teaching anatomy, and, indeed, this is not its first introduction to the American public, as some years ago Dr. G. H. Napheys prepared and had published a similar "movable atlas," or some plates of one. We believe, however, that it did not turn out to be a popular mode of study. The present one is larger, and the text sufficiently full for popular instruction, for which, apparently, it is chiefly designed. Indeed, for the general reader or for schools this series merits strong praise. But if any medical student tries to make it take the place of steady, plodding, laborious dissecting, he will commit a grave error.

BOOK NOTICES.

Transactions of the Medical Society of the State of Pennsylvania. Vol. xiii. Part i. 1880.

This part makes in all a volume of nearly 500 pages. One half of this is filled with the regular minutes, reports and addresses; the remainder with county reports and rosters. As we gave at the time of the meeting a sufficiently full account of the former, we may now devote most of our attention to the county reports, which are not read before the Society, but are forwarded to the Publication Committee.

These reports are an excellent feature, and we know of no other State society which gives them so much attention as that of Pennsylvania. A printed form is furnished for them, but this is not, and need not be, generally adhered to. It is rather intended as a series of hints to guide local researches. We regret, however, to see this distinctive and admirable feature showing signs of atrophy. Omitting the Obituary notices, and the Philadelphia Society, the reports from the State at large hardly make up a hundred pages. In these are several articles which well merit the reader's attention; we refer to several cases of renal disease, by Dr. G. W. Smith (p.

251); the etiological relations of phimosis and præputial adhesions to epilepsy by Dr. D. F. Unger (p. 296); a case of empyema, by Dr. D. J. M'Caa (p. 315); a case of recovery after ovariotomy, by Dr. S. T. Davis, (p. 317); a case of spinal bifida, by Dr. A. B. Blair (p. 414); and others

The reports and voluntary papers which precede the county society reports are especially full and of a high order of merit. It would give us pleasure to enumerate them, but the space at our command prevents us.

Transactions of the American Medical Association. Vol. XXXI. Philadelphia, 1880.

This year the transactions make up a bulky volume of nearly 1300 pages. It is, we believe, the largest yet issued, and certainly it presents more numerous papers and more complete reports —taking the list of them—than any previous volume. The Sections are constantly rising in value as accessory bodies to the parent association. It is a satisfaction to add that most of the papers are such as merit preservation in this permanent form; most of them, we say, for few will deny that several of the articles are very lightly weighted with anything new or valuable, and at most, would deserve to see the light in some of the countless journals of the day. The pruning knife is visibly needed in the hands of the publication committee, or wherever it is that the grave responsibility of using it rests.

It would be a pleasure to specify a number of articles of exceptional interest in this volume. But, on noting them for that purpose, we find so many that it is better to recommend the reader to turn its pages for himself, for in whatever branch of the profession his interest especially centres, he will certainly find something to fasten his attention.

Much credit is due to the publication committee for the care and taste evident in the make up of the volume and its typographical disply. All that involves an amount of dreary labor, of which the general reader has no conception.

A Manual for the Practice of Surgery. By Thomas Bryant, F.R.C.S., etc. Third American, from the third revised and enlarged English edition. Edited by John B. Roberts, A.M., M.D., etc. With 735 illustrations. Philadelphia. H. C. Lea's Son & Co., 1881. Half Russia, pp. 1005.

The intrinsic merits of Bryant's *Surgery* have led to a steadily increasing popularity, both in England and this country. He is a clear, compact writer, reminding one somewhat of Syme, and an operator of acknowledged skill and originality. Without freighting his book with multiplied details and wearying descriptions of allied methods of procedure, he is ample enough for reference on all the departments of surgery, not omitting such strict specialties as dental, ophthalmic, military, orthopædic, and gynæcological surgery. Some of these chapters are written by specialists in these respective branches, and all are amply sufficient for any one not himself aiming at special practice.

The labors of the American editor deserve unqualified praise. His additions to the author's text are numerous, judicious and germane. They add very distinctly to the value of the original treatise, and give a more equitable illustration of the part taken by American surgeons than the author was able to do, owing to his less familiarity with our current literature.

The book is excellently printed, and as it can be had in the half Russia binding introduced by the publishers, its manufacture will satisfy the most critical.

Cyclopædia of the Practice of Medicine. Edited by H. von Ziemssen. Vol. IX. Diseases of the Liver and Portal Vein. With the chapter relating to Interstitial Pneumonia. Wm. Wood & Co. New York City, 1880.

This is the final volume of Ziemssen's Cyclopædia. The publishers are to be congratulated on getting through with it in a manner so satisfactory to their subscribers, and we trust, to themselves. It was a vast undertaking, with reference to cost and labor, and, as the publishers show in a circular, it has exceeded the original estimate by over 4000 pages.

As to whether an advantage to medical science in this country has been achieved, of corresponding magnitude to the commercial aspect of the enterprise, there is serious reason to doubt. The wordiness and theorizing of German writers, their tendency to dwell inordinately on insignificant points, and the distinctly speculative (using that word in its philosophical sense) character of their therapeutics, are traits that it would be unfortunate for us to adopt in the United States, and we hope the *Cyclopædia*, which is far from being free from these faults, will not have introduced them—at least, not to stay.

Nevertheless, it were vain to deny the vast amount of instruction contained in this great work, and we should be the last to do so. Recognizing it fully, we believe that, on the whole, such a translation is less useful than a judicious abridgment would have been. While we consider this the best of its kind, we hope the experiment will not soon be repeated.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE LIMITS OF A PHYSICIAN'S DUTY.

The physician who looks upon his calling as something more than a business recognizes that it, more than most, has to deal with important sociological questions. We familiarly call the defined result of various observations in physiology "Laws of Health." They are not laws in the forensic sense of that term, hardly so in its scientific sense, because on the one hand the government concerns itself but little with enforcing them, and on the other they are repeatedly disregarded without any injurious result following. Men daily expose themselves to draughts, sit in wet feet, or neglect their secretions, and escape any untoward consequences.

When it comes to matters of greater moment, where the evil is at any rate more conspicuous and the relation of cause and effect more apparent, the question arises how far ought the profession, as such, to advocate governmental interference. A living issue of this kind is the use of alcoholic drinks as a beverage. There is no difference of opinion that they do more harm than good; indeed, that they are a potent factor in the physical degradation of a nation. Is it a part of our duty, as physicians, to express ourselves, as a body, against their manufacture and sale?

Take another subject, no less actively discussed in many quarters, the prevalence of prostitution. For a number of social reasons it appears to be on the increase in all our large cities. That it is a very fertile means of the extension of disease and greatly aids in the physical depravity both of the woman herself and those who patronize her trade, nobody denies.

What is worse in both these cases, the efforts which, in this country at least, have been made to diminish the evil consequences of liquor dealing and whoremongering, have been of little or no avail; less, perhaps, owing to any defect in the character of these efforts, than in the ability to carry them out honestly and systematically.

No doubt here, as in the false elocution of the players which Hamlet criticised, the proper way were to reform, not indifferently, but altogether. Can this be done by legislative power? Is it a part of the profession's duty to urge it on legislatures?

It is by no means clearly so. The tendency of all modern law-making has been against sumptuary enactments of every description. The uniform experience of history has proved them unsuccessful and inequitable. A decided majority should be willing to receive such a law and to aid in enforcing it before it is spread on the statute book. What is called the "interference theory of government," has few defenders among intelligent statesmen.

In all such examples we believe the activity of the profession has reached its limit when it enlightens the masses as to the danger of violations of health rules, and thus prepares the public mind to protect itself. Self-government, self-control, these are the true aims of all education, all government, and they alone are trustworthy guarantees of action.

In another direction the limits of a physician's action seems to require definition, that is, as toward religion. This is a delicate, a burning question, and we broach it with caution.

Nothing so quickly excites all a man's bad passions as to pinch his religious prejudices. But the inquiry is often made, and should be answered, how far a physician's religious views should enter into his avocation.

The editor of the Edinburgh *Medical Journal*, in a recent issue, expresses an opinion on the subject in the following language:—

The healing art takes precedence of all other human occupations. The clerical profession may occur to most minds as preëminent; but it is manifestly unable to cope with those disorders, bodily and even mental, to which our human flesh is heir, while, on the other hand, there is nothing to hinder the medical man, who does possess that power, to minister also, if he is at once religious and earnest, to the spiritual wants of his patients. Who, we would ask, gains and possesses the confidence of the dying man so thoroughly and rightfully as he who, with skill and sympathetic tenderness, has been attending to his bodily injuries and sufferings? We do not say that this possibility is actually realized so frequently, so systematically, as it ought to be, even by those who acknowledge it; but we hesitate not to aver that it exists, and even now may be seen in ample development, both in our own crowded cities and in many remote missionary fields.

We must express our dissent from the intimation of duty here conveyed. We do not think it any part of the physician's duty "to minister to the spiritual wants of his patients." We go further, and say that only in rare and exceptional cases has he any right to yield even to solicitation to do it, because he cannot do it honestly. The most any one can say under such circumstances is confined to bare and vague generalities. A physician of earnest religious convictions must utter them, if he speaks at all. Is he an ordinary Protestant, he will have patients who are Catholics, or Jews, or Unitarians, to whom any full expression of his religious consolations will be inapt and repellant. Does he himself belong to one of the other sects we have named, nothing he can say to an ordinary Protestant is likely to appear appropriate or agreeable.

In fact, nobody wants religious consolation other than the kind he has been accustomed to. Suppose the physician is a disciple of Comte, or Spencer, or Renan, or Bob Ingersoll; then the editor of the Edinburgh *Medical Journal* would readily excuse him from proffering the kind of consolation those philosophers are prepared to dispense. So, we think, other folk, who have not the privilege of belonging to the kirk, will be quite willing to allow the physician to stick to his pills, the priest to his breviary, and the shoemaker to his last.

Notes and Comments.

Metastasis in Mumps.

One of the most mysterious pathological sympathies is that of the parotid gland with the organs of generation. In the male, sympathetic orchitis is not rare; and in the female the whole generative system may be involved. Dr. Good says, "In advanced life parotitis is sometimes apt to run into a chronic form, accompanied by very mischievous symptoms. This is most especially apt to take place in females when menstruation is on the point of ceasing, and the general action of the system labors under some disturbance." Copeland, under the head of "Parotid Glands," adverts to the fact that parotitis, occurring in the female about the time of puberty, is apt to be very difficult to treat. Dr. S. Ringer, in Reynolds' *System of Medicine*, says that, "In the female, the mammæ, the labia majora and uterus are the parts occasionally attacked." On the other hand, there are not wanting observations in gynæcology to show that uterine disturbances give rise to inflammatory swelling and functional impairment of the parotid gland. After various operations on the uterus, parotitis sets in as a complication. The subject deserves closer study than it has yet received.

The Perivascular Lesions in Hydrophobia.

It is well known that some pathologists have maintained that certain perivascular lesions in the nervous system are characteristic of hydrophobia. Dr. Middleton, of Glasgow, lately stated to the Pathological Society of that city, that in two cases of hydrophobia he had found the perivascular lesion described by previous observers, and he had been led to examine the nervous structures in other cases, with a view to find out whether this lesion was in any way characteristic. Of twenty-four cases examined, fifteen showed this perivascular lesion, some of them in a form almost quite as marked as in hydrophobia. Sixteen cases had had more or less cerebral symptoms, delirium, etc., and only four presented no vascular lesion; among these were cases of fracture of the skull, erysipelas, delirium tremens,

diabetes, tubercular meningitis, uræmia, etc. The frequency of the lesion in so many diverse diseases was held to indicate that it could not be attributed to any special irritant in the blood, but rather to nervous excitement; and the investigations seemed to point to the fact that the intensity of the lesion varies directly with the intensity and duration of the cerebral excitement.

The results are published in full in the *Journal of Anatomy and Physiology*, October, 1880.

Hysteria in a Male Child.

MM. Bourneville and D'Oiller have published, in *Le Progrès Médical* for November 20 and 27 1880, an account of a case of hystero-epilepsy in a boy of thirteen, as a contribution to the study of hysteria in the male sex. This boy had hemi-anæsthesia of the right side, affecting the special senses, and partial color-blindness. There were numerous hysterogenic zones or areas, pressure upon any of which was followed by a fit. These fits were epileptiform, being preceded by an aura. and having their stages of tonic spasm, clonic spasm, and delirium. The boy's mind was never affected. Metallic bracelets and magnets caused transference of the hemi-anæsthesia, but could not effect a cure. Attempts to hypnotize him failed. He was cured by the douche.

Slow Development of the Physical Signs in Pneumonia.

An interesting debate recently took place at the Clinical Society of London. One member, Mr. Tyson, quoting Ziemssen's statement that up to the third day after the chill percussion over the affected part becomes dull and broncophony appears, etc., said that such was not his observation. He added:—

"From my present experience of pneumonia, and seeing the disease as I do in its earliest stages, I believe that the physical signs, such as dullness on percussion, bronchial breathing, and bronchophony, occur later in the course of this disease than is usually supposed, or perhaps it would be more correct to say that there is a larger percentage of cases with the above lately-discoverable physical signs than our reading and teaching have led us to think."

Dr. Andrew Clark said that his desire was to enforce the impression that in a large percentage of cases the physical signs only became marked towards the close of the disease, when it had nearly run its course, and that consequently practitioners must, in coming to their conclusions, be largely guided by general indications.

Dr. DeHavilland Hall narrated some cases where for days the absence of physical signs had made him doubtful of their nature. He thought that those cases where the physical signs appeared late were more severe than those where they appeared earlier, having to spread from within the lung toward its surface.

It is well for all practitioners to remember that implicit confidence cannot be placed on the magisterial statements of many of these German writers. They have the national tendency to force facts into accordance with their theories.

Chorea in Pregnancy Treated by Dilatation of the Cervix Uteri.

At a late meeting of the Obstetrical Society of London, Dr. Wade reported an interesting case. An unmarried primipara, æt. 19, nearly seven months pregnant, suffered from very severe chorea, which had commenced in a slight form three weeks before admission. A faint apex systolic bruit, probably due to rheumatic fever two years previously, existed. An attempt was made to dilate the os with the finger, but owing to the incessant and violent movements of the patient, the success was very partial, and there was, if anything, an exacerbation of the symptoms. Three days after, under chloroform, the dilatation was completely effected; this was followed during the day by very marked amendment, and a sound night's sleep, the first she had had since admission, and every succeeding night was equally good. On the third day after the movements became worse than they had been on the two preceding days, and dilatation was again effected on the fourth day, under chloroform. From this time steady, rapid and unintermittent recovery supervened. A very slight occasional twitching of the fingers of the right hand continued until delivery, at term, of a healthy child, when they entirely ceased.

Hot Water Compresses in Tetanus.

Warm or hot baths in tetanus have frequently been found to give great relief; but in many circumstances it is practically impossible to give them. In view of this, in the treatment of tetanus and trismus, Dr. Spoerer has successfully employed hot-water compresses. He dips a large enough piece of coarse flannel in water of a temperature which can just be borne by the hand (50° to 55° C.), and applies the compress to the occiput and along the spine.

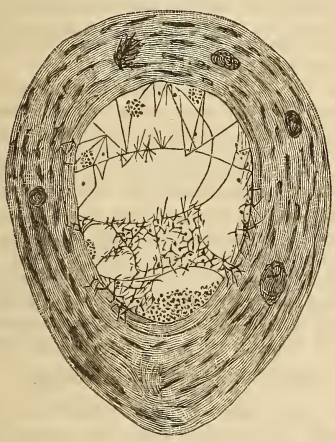
Special Reports.

V.—SYPHILOLOGY.

The activity in this branch is surprising, and we can give but brief analyses of a number of valuable papers which have appeared in the last few months. Beginning with etiology, we refer to

The Fungus of Syphilis,

or what is supposed by some to be such, as described and figured by Dr. Bermann, of Baltimore, in the *Archives of Medicine*, December, 1880. It is a variety of micrococcus, classified by Prof. Klebs with the *schizomycetæ*, but by Dr. Bermann with the myxomycetæ. It is represented in the following cut.



Section of an arteriole containing the branching fungus and spores found in chancres. Drawn from a preparation of Dr. I. Bermann, by Dr. R. W. Amidon. Objective $\frac{4}{10}$ Tolles.

The infection takes place by reason of a few germs of micrococci being retained in a lesion of the skin. They are taken up by the lymphatics, and here they increase and multiply, spreading principally in these, and soon begin to obstruct the circulation in them.

We shall refer later on to Dr. Bermann's theory of treatment, based on these observations. He is still pursuing his investigations, and we doubt not will obtain important results, both theoretical and practical.

The close relations of syphilis to profound impairments of the nervous system has recently attracted much attention. One of the most notable papers is on

Syphilis as the Cause of Locomotor-ataxia,

which appears in the *Medical Press and Circular*, Nov. 24th, Dec. 1st, from Dr. Thomas Stretch Dowse, Physician to the Hospital for Paralysis and Epilepsy, London. This writer has had extensive opportunities for observation, and the decided statement with which he begins his article will surely surprise many. It is as follows:—

There can be no doubt, unless we have contrary proof of the most absolute and positive kind, that irregularity of movements and disturbances of volition, either in the engenderment of ideas or in the performance of coördinate muscular acts, are, in a very large majority of cases, due essentially to some syphilitic affection of the nervous centres. With this fact the clinical observer is becoming every day of his life more familiar, and it is a misfortune of the most serious nature to the patient when these symptoms and signs of incoördination are treated as mere trifles, and thought to be due merely to fatigue, or to stomach or liver derangement. I have no hesitation in making the statement that every case of locomotor-ataxia is curable, provided it be treated sufficiently early, and in the most energetic manner. Every case of locomotor-ataxy (with very few exceptions) can be traced to a syphilitic origin, if due care be taken to inquire carefully into the patient's history.

The pre-ataxic stage here referred to can be distinguished by the general symptoms of nervous break down; but there is one which is pathognomonic. Dr. Dowse says:—

Of these various signs there is only one upon which I place the most absolute reliance from a diagnostic point of view, and that is the fulgurating pains; and patients will often describe them to me, as though a fine lancet which had been made hot had been driven into the skin for about an eighth of an inch. These pains are not limited to the lower limbs; they may attack the head, the nose, the ears, the shoulders, the buttocks, and the scrotum, and even the penis, but as the disease advances and the ataxia becomes pronounced and decided, the legs alone are the seats of pain. I had a patient under my care a few months since who spoke of these pains as resembling the sting of a horse fly. These pains succeed each other with the greatest rapidity; they occur for the most part singly, and the patient has scarcely time to rub one part of the body before his attention is called to another part. Now these pains may be preceded and succeeded by intense itching over a limited and circumscribed area, and this state of itching will be as rapidly migratory as were the pains just described; and if we test the sensibility of the skin of the feet and lower limbs we shall find patches which are decidedly anæsthetic; but this is more particularly marked over the plantar and dorsal surfaces of the feet and inner part of the legs.

Another asserted etiological relation exists between

Syphilis and General Paralysis of the Insane.

While this has been frequently alleged, considerable doubt has been thrown upon it by Dr. Christian, in the *Union Medical Journal*, 1880. He gives notes of eight cases in which syphilis

and general paralysis were co-existent, and comes to the conclusion that anti-syphilitic treatment, however thoroughly carried out, only cures the syphilis, but has no power over the paralysis. Thus, Dr. Christian concludes that syphilis goes for nothing in the causation of general paralysis. Doubtless, in the complex etiology of general paralysis, it may be admitted that syphilis, as a debilitating constitutional disease, may be, in those predisposed, an accessory or secondary cause of the paralysis. Doubtless, also, syphilitic brain disease, which is very variable in its forms, may simulate more or less the symptoms of general paralysis, but it never appears as true general paralysis. Between the two, there is nothing in common. This is so true, that the disorders often progress side by side in the same patient without mixing, and *post-mortem* one finds, together with the alterations due to general paralysis, lesions peculiar to syphilis, such as gummata of the brain itself, or of its meninges.

This view is also supported by Dr. C. Drysdale, in the *British Medical Journal*, August 28th. He considers that syphilis is an occasional, though rare, cause of mania, dementia, and melancholia, but not of well-marked paralysis of the insane. In the majority of cases syphilis attacks the brain; it impairs the intellect more or less. Sometimes loss of intelligence is one of the first symptoms.

Syphilitic Neuralgia.

The substance now employed by Prof. Zeissl, in this form of neuralgia, is *iodoform*:—

℞. Iodoformi, gr. xxij
Extracti gentianæ,
Pulveris gentianæ, āā q. s. M.

Make twenty pills. Two or three to be taken daily.

Syphilitic Jaundice.

Though not a frequent manifestation of the secondary stage, there is no doubt but that jaundice is occasionally directly due to the syphilitic poison. A very clear case is recorded by Dr. *Soler y Buscalla*, in the *Revista de Ciencias Medicas* for January, 1881. A youth of twenty-one years was admitted with swollen inguinal glands, cutaneous syphilides and a history of a primary chancre some months before. There were no gastric troubles nor febrile symptoms. Under a strictly anti-syphilitic treatment—protiodide and ferruginous syrup of quinia—the icterus disappeared. Dr. S. adds that none of the current explanations of syphilitic icterus are more than mere hypotheses, and it remains a pathological enigma.

Malignant Syphilis.

The existence of "malignant syphilis" seems clearly established—a form of the disease running its course rapidly and in spite of the most active treatment. A semi-malignant case is reported in the London *Medical Times and Gazette*, Dec. 18, from the London Hospital.

A man, fifty years of age, contracted syphilis in October. About the beginning of December ulceration attacked the left ala of the nose, and continued rapidly to spread until nearly the whole left side of the nose was involved, the lower portion of the right ala, and a considerable portion of the left cheek. When admitted, May 1, the left nasal bone and part of the upper maxilla were exposed, and all the surface named was sloughy and unhealthy. On the scalp there was a continuous cicatrizing surface from the centre of the forehead to the occipital protuberance, and a scar over the left temporal region. Patient was bald before the attack, so that these scars and ulcers were well seen.

Iodide of potassium was administered internally, and subsequently iron and quinine were given. Iodoform ointment was used as a local application. Under treatment the ulcers on the head rapidly healed, but at first the disease of the face was rather obstinate.

On May 18 it was noted that the ulcers on the scalp had quite healed, but that the phagedæna of nose and face had apparently extended. Iodoform powder was then dusted on these parts, and the wound assumed a healthier appearance.

Patient was discharged in the beginning of June, with the disease almost entirely arrested.

Syphilitic Diseases of the Lungs.

These have recently been studied by Prof. Gamberini, of Bologna, whose article appears in the *Gior. Ital. del. Mal. Ven.* His results are that the existence of a simple inflammatory syphilitic pneumonia may be admitted, but is not yet conclusively proved. The occurrence of a gummy form of disease of the lung is established beyond doubt. True pulmonary tuberculosis may be associated with syphilis, but it preserves always its own pathological characters. To distinguish between the syphilitic and the tubercular forms of lung affection, the author proposes for the former the title of "consumptive pulmonary syphilis." The influence of specific treatment is, at the present time, the best therapeutic means of diagnosis between tubercular and syphilitic disease of the lung. Prof. G. agrees with Schnitzler, that pulmonary disease as a consequence of late general syphilis, or even of acute secondary syphilis, is not a rare occurrence. Laryngeal lesions often precede or accompany syphilitic pulmonary affections. This has been proved by the observations of Schnitzler, who, indeed, affirms that the diagnosis of spyhilitic lung disease may be made by means of the laryngoscope alone. The symptoms

of syphilis of the lung are generally those of pneumonic phthisis, from which, during life, there may be no certain means of distinguishing it; even after death, the distinction cannot always be made between gumma and tubercle, especially when the gummy nodules are in a state of caseation, or are infiltrated. Syphiloma most usually spares the apex, whereas tubercle most frequently attacks that portion of the lung. This, however, is not constant, as has been shown by Fournier. The course of pulmonary syphilis is usually slow and apyretic, which is not usually the case in tubercular phthisis. Syphilis, also, is accustomed to attack only one lung, and one part of the lung. This tendency to localization is considered by the author to be a very important point in the diagnosis of pulmonary syphilis, whether the lung be attacked at an early or at a late stage of the disease.

Syphilitic Iritis.

This much feared complication requires prompt action. The treatment recommended by Mr. J. R. Wolfe, surgeon to the Glasgow Ophthalmic Institution (*London Medical Times and Gazette*, January 1st), is as follows:—

After the administration of pil. hydr. c. colocynthidis, I order small doses of ol. terebinth—one teaspoonful three times a day in syrup. aurantii. It was recommended by Dr. Carmichael, and was the favorite remedy of Dr. M'Kenzie. This I continue for three or four days, with warm drinks, foot-baths, etc. Then I order pil. hydr. c. quinæ three or four times a day, and the unguent. hydr. fort., into the armpit, ʒj. every evening; warm baths twice a week. When the gums begin to get tender, I discontinue the pills, and only apply the unguent. hydr. to the axilla, and internally potassium iodide is ordered. Should symptoms of mercurialization supervene, I discontinue the ointment and keep the patient exclusively to potassium iodide, which may be given ℈j. three times a day. The strong atropine solution, with the gray ointment, is continued for a considerable time. The drops may even be persevered with for a month after the general inflammatory symptoms have disappeared.

Syphilitic Gummata of the Iris.

The latest study of this subject is by Dr. E. Nitot, *Des gommes syphilitiques de l'Iris et du Corps Ciliaire*, Paris, 1880. His discussion leads to the following results:—

Every malignant tumor of the ciliary body in a syphilitic subject should be considered as a gumma. Every malignant tumor of the ciliary body in a non-syphilitic subject is probably either a melano-sarcoma or a tuberculous tumor. Although a gumma is destructive, and in this sense malignant (heterologous), it can usually be dissolved by iodide of potassium, and is not liable to return. Gummata of the iris are much more frequent than those of the ciliary body, and yield readily to anti-syphilitic remedies.

Gummy Tumors.

The subject of syphilitic affections of the eye, especially gummy tumors, is also discussed by Dr. C. Arago, in the *Revista de Ciencias Medicas*, January 1881. He especially calls attention to the importance of an early diagnosis, and of their treatment by improved pharmacal methods. Mercurial fumigations he considers injurious and dangerous. He slightly salivates with fractional doses of calomel supported by infusion of jaborandi, and maintains it by such a combination as—

℞	Protiodide of mercury,	10 centigrams,
	Iodide of potassium,	8 grams,
	Water,	300 grams. M.

A spoonful with a few mouthfuls of infusion of jaborandi two or three times a day.

Very decided improvement is visible after a week or two of this treatment, and a complete cure is sure to be effected.

Syphilis as a Cause of Cataract.

The eminent ophthalmologist, Professor Galezowski, advanced the opinion, in the *Recueil d'Ophthalmologie*, Sept. 1880, that syphilis may cause cataract in the adult primarily, or predispose to it hereditarily. He gives details of a case of kerato-irido-choroiditis in a child of four years of age affected with syphilis from its birth. In this case, a cataract became developed, and the eye was enucleated. The author has seen, in all, nine cases of congenital cataract in children born of syphilitic parents. As regards the effects of syphilis in the adult, he has frequently seen cases of monocular cataract affecting an eye in which there was syphilitic choroiditis, while in the other eye the lens was perfectly transparent. He gives details of a case of syphilitic choroiditis attacking one eye, followed by the development of soft cataract six months afterwards in the other.

In passing to the subject of treatment we may first mention

Treatment of the Primary Sore.

Dr. Bermann, in the article above mentioned, recommends that the fungi be destroyed by *hypodermic injections of mercurials*. He says of them:—

When properly made, these injections are not painful, and never produce abscesses unless the syringes are unclean. Even in cases where a quick mercurialization had to be resorted to (for instance, in iritis specifica, where the gumma was touching the membrana Descemetii), I have had

the most perfect results with them, never observing any relapses nor producing salivation. At the same time, we are thus enabled to derive the full benefit from any other kind of medicine (such as iron, etc.) given by the mouth, and do not run the risk of disturbing gastric digestion by giving mercury internally.

The plan of *excising the sore* recommended by various German surgeons, was reviewed in the *Annales de Dermatologie*, last July, by Dr. Chadzynski. He reported thirty cases from his own practice. The part was first washed with a solution of carbolic acid (3 or 4 per cent.). The induration was next laid hold of with the fingers or forceps, and, under the spray, the whole indurated portion was removed. Sutures were then inserted, according to the size of the wound, and carbolic lotion or iodoform applied. In only six of the thirty cases did primary union take place. In five, induration reappeared, but the cicatrix sometimes remained free from hardness, even after the appearance of secondary symptoms. Seven cases were successful, sixteen were unsuccessful, and, in the remaining seven the result was unknown, owing to the disappearance of the patients. Of the successful cases (those in which there were no signs of constitutional syphilis), two were kept under observation for six months, three for seven months, one for thirteen months, and one for more than twenty-four months. In all the seven there was more or less enlargement of the corresponding lymphatic glands at the time of the excision of the sore.

It must be acknowledged that this result does not encourage one to rely on the operation.

Syphilitic Ulcers.

Good success has been obtained by Vidal in obstinate syphilitic ulcers by the following:—

R.	Acidi pyrogallici,	1 part.	
	Ung. petrolei,	5 parts.	M.

It succeeded when other measures failed, and also acted well on chancroids. It causes slight pain for five or ten minutes (*Archives of Dermatology*, Oct. 1880).

As a final resort the *thermo cautery* may be employed; we quote the following very interesting case from the Glasgow *Med. Journal* for January, 1881, from the Glasgow Royal Infirmary:—

John Rilley, a shoemaker, was admitted to Ward XIII on 16th May, with an ulcer on the lower lip. The history of the case showed that he had contracted syphilis three years before, and had suffered from the usual sequelæ. He was treated by a medical man for some time. Shortly after the treatment was discontinued an ulcer appeared on the lip, but this healed up perfectly on the treatment being resumed. Again, after a few months the lip broke out and gradually became worse, notwithstanding the use of the anti-syphilitic remedies which had proved efficacious before. This went on for two years, treatment being resorted to at intervals. On admission, there was observed an ulcer somewhat excavated, the edges raised, hard, and evolved, discharging a fetid pus, and exquisitely painful, extending over the whole of the outer surface of the lower lip. The patient had a dusky, ill nourished, syphilitic look, and the inguinal glands were hard and rolling. He was put upon iodide of potassium, with bichloride of mercury, and a lotion of chloride of zinc was applied to the sore. At the end of a fortnight there was not the slightest improvement, when Dr. Dunlop had the patient put under chloroform, and destroyed the surface thoroughly with the thermo-cautery. After this, pain was never complained of, and the sore healed up kindly. The bichloride and iodide were still continued and a simple water dressing applied.

He was discharged 25th June, perfectly cured. This case is an example of a syphilitic sore taking on a certain degree of local malignancy, so that it resisted all ordinary treatment for that disease, and yielded readily on the destruction of its surface.

Syphilitic Psoriasis,

As it occurs on the palms of the hands and soles of the feet, is generally very obstinate and resists mere constitutional treatment. A writer in the *Lyon Médicale* recommends that preparations of *corrosive sublimate* should be painted once or twice daily on the papules, pustules, and crusts, after bathing the parts; compresses of solution of acetate of lead will lessen pain and prevent irritation. For lesions in the soles and palms, the best excipient in which to prescribe the sublimate is collodion; for tender parts of the skin and for the slighter manifestations of syphilis, alcohol; for lesions of the mucous membrane, ether.

Very obstinate palmar or plantar psoriasis should be painted every morning with an application consisting of one part of corrosive sublimate, one of fresh linseed oil, and fifteen to twenty-five of collodion. In the evening the parts should be energetically rubbed with white precipitate ointment (one part of ammoniated mercury to five of simple ointment).

In cases marked by deep fissures and considerable infiltration, local baths with a 2.5 per cent. solution of carbolic acid, or a five per cent. solution of chloride of potassium or sodium, or rubbing with zinc ointment or sparadrap de Vigo, will be found useful.

Turpentine as an Anti-syphilitic.

Some interesting experiments with this are detailed in the London *Medical Times and Gazette*, Dec. 11, 1880, by Dr. B. Nicholson. A soldier had been treated by iodide of potassium for a syphilitic *plaque* below Poupart's ligament.

Freed from all appearance of disease, he was, after due caution, discharged with three days' convalescence. Almost immediately, however, after his return to duty, he re-appeared before me in the same state as at first. On this I changed the treatment, and gave him half a drachm of turpentine thrice a day, made into an emulsion with water and liquor of potash. Under this he rapidly got well, was discharged, and did not return.

Of course, I was led to give turpentine a more extended trial in buboes, suppurating and non-suppurating, and in syphilitic orchitis, etc., but without effect. Some two or three years afterwards I was shown, by a medical friend, one case of plaque, and another of syphilitic orchitis, both of which had resisted treatment. I narrated my experiences and turpentine was tried. The plaque case got well; the orchitis remained unaffected.

I took charge of a man recovering from the last of several relapses of *syphilitic iritis*. He had been somewhat profusely salivated, and the salivation continued. Before it ceased he had another relapse. I gave one-drachm doses of turpentine, using belladonna or atropine locally. The result was a speedy cure. Afterwards, the salivation having ceased, he had another attack. Turpentine was given, but without effect, and I was obliged to have recourse to mercury, under which he recovered. In other and more ordinary cases I did not find turpentine of any use.

Bichromate of Potash in Obstinate Syphilis.

In those obstinate cases whose progress cannot be checked by the ordinary remedies, Dr. F. Arpal recommends the bichromate of potash (*La Union Medica de Aragon*, Nov. 1880). He begins this potent poison in doses of one centigram daily, in an opiate vehicle, cautiously increasing it to four centigrams daily. He has observed relaxation of the symptoms in four or five days, and a complete restoration to health follow. These were cases of undoubted and progressing syphilis, which were not benefited by mercurials or iodide of potash.

In discussing the theory of its action, he believes that it is through its powerfully oxydizing agency that it alters the condition of the system. It is also a decided anti-zymotic, and may destroy the syphilitic fungus.

Correspondence.

Medical Matters in Vermont.

State Medical Society Meeting; Legislature Regulating the Practice of Medicine and Surgery; State Board of Health; Comments on Dr. Corson's Article.

Ed. Med. and Surg. Reporter :—

The Vermont Medical Society holds two meetings during each year. The annual meeting is always held at Montpelier, the Capital of the State, and on the second Wednesday and Thursday of October. The semi-annual is held in different parts of the State; last year at St. Albans, this year at the city of Vergennes. Both meetings are quite largely attended from all parts of the State, though the interest of the profession in them is not what it ought to be. The meeting at St. Albans was interesting, on account of the excellent papers that were read and the discussions that followed. Diphtheria and typhoid fever are fruitful subjects for discussion, and always call out an immense amount of theory which shows a wider difference of opinion than exists in practice. The therapeutics of these diseases and their kindred are better understood, or there is more general agreement upon methods of treatment than upon the cause which produces the disease. All agree that, to a large extent, they may be prevented by proper sanitary and hygienic regulations. This session of the society was attended by the professors and students of the Medical Department of the University at Burlington, and Professors Settle and King read very interesting papers. Dr. J. H. Warren, of Boston, read a paper upon the method of curing hernia by hypodermic injection of the hernial ring, and performed the operation upon a patient before the Society. The operation was completely successful. Dr. Warren explained fully his method of performing the operation, and communicated the formula for the substance injected.

The annual meeting for 1880 was held during the session of the Legislature. Four years ago an Act regulating the practice of medicine and surgery was passed by the Legislature, which was fairly satisfactory to the profession, including the Homœopaths and Eclectics. Censors were appointed by all the State Medical Societies, and as a result a large class of itinerating quacks were driven from the State, not having, nor being able to obtain, a license to practice medicine in the State. Two years ago, through the lobby influence of this class, and their friends in the Legislature, an amendment of the Act was passed, which practically opened the door for the readmission of the whole horde of quacks into the State. And they have improved the opportunity. The law being thus practically nullified, the State Medical Society petitioned the Legislature to repeal the law. And it was done at the last session. An effort was made at the late session to enact a law more stringent than the one repealed, and similar to that of New York, and perhaps, of other States. It met with the most furious opposition, mainly from the Homœopaths and Eclectics, very few of whom have a diploma from any Medical College of any kind. It was ably advocated in the House, where it originated, but failed to pass. Another two years of quackery in the State will, we trust, so change the tone of public sentiment on this subject that the passage of a law requiring at least some show of knowledge of medicine and surgery in the practitioner, will be a popular demand. Till that time passes, quackery will have full swing all over the State. It is fair to say that some members of the profess on in the State have no confidence in such legislation. They would prefer to have the fraternity stand upon its own merits, raise the standard of preliminary and medical educa-

tion, and guard the door into the profession against the admission of any one who is not thoroughly qualified in all its branches. The Medical Department of the University at Burlington is taking high ground upon this subject, and to its credit, it is becoming widely understood that no novice or ignoramus in academic or medical education can pass the severe ordeal of its examination. With such schools for medical instruction in all the States, the profession will ere long occupy a much higher vantage ground than it now does, and suppress quackery by the force of superior education.

For several years past efforts have been made to establish a State Board of Health and Vital Statistics. Two years ago the bill passed the Senate unanimously, but was lost in the House. In the last Legislature it passed the House by a large majority, but was lost in the Senate, ostensibly for want of time to consider it, the bill reaching that body late in the last evening of the session, but really, if we are rightfully informed, for reasons not quite so reputable to honorable Senators. It was on this wise. The bill was advocated with great ability and earnestness in the House. by several of its most prominent members. One member, in his zeal, overstepped, perhaps, the bounds of debating courtesy, and declared that no man of common sense would vote against the bill. This, with other remarks still more pointed, gave offence to certain Senators who happened to be in the House during the debate, and who, on returning to their seats in the Senate, passed the word around the chamber that the House was attempting to "bulldoze" the honorable Senate into the passage of the Health bill. When the bill reached the Senate the fever was at its height, and the bill was "indefinitely postponed." The Senate of Vermont is usually the conservative, deliberative branch of the Legislature, but it did not maintain its usual reputation in that direction this year. The friends of a State Board of Health for Vermont are not discouraged. They feel confident that another session of the Legislature will accomplish the object, and place the Green Mountain State in line with other States of the Union in the grand work of preventive medicine.

I have just read. with pleasure and profit, the first installment of Dr. Corson's article in the REPORTER of Jan. 15th. The views of pneumonia he presents are worthy of consideration. In the early part of my professional life I was in the practice of blood-letting for every disease that assumed an inflammatory type. The practice then was to bleed in fevers, and especially in pneumonia, and to follow the bleeding with purgative doses of calomel and jalap in the former, and with tartar emetic in the latter. Some were cured, of course, or got well, but many died. In later years I have adopted a different course. I have laid aside the lancet, not discarding its use, but holding it as a kind of *corps de reserve*, to be used when necessity demands. In its stead I now use *veratrum viride*, sometimes alone, and sometimes with *aconite* and *morphia*, one or both. The first stage of pneumonia, in my opinion, is congestive, not inflammatory; that comes as a sequence of failure to control the congestion. Take the symptoms Dr. Corson mentions in his typical case. Instead of bleeding, as he suggests, I would prescribe veratrum viride in tinct. or fluid extract, with aconite, and I should expect before the patient had taken many doses of it his pulse would come down from a hundred to seventy, and perhaps fifty; he would breathe freely; his flushed, anxious face, as if suffocation were imminent. would have disappeared; his cough would be subdued; perspiration would break out all over him, and in a few days' time he would be about his daily avocation, having lost but little of his strength or vitality; bounding up from the deep depression of a threatened fever or inflammation. Having tried both methods of practice faithfully, I am satisfied that more patients can be saved from the jaws of death by veratrum than by the lancet. It is very seldom that I have a case of pneumonia in my practice. With the treatment I pursue they seldom reach that stage, and if they do, the disease is arrested before it reaches the next stage. L. C. BUTLER, M.D.

Essex, Vt., Jan., 1881.

NEWS AND MISCELLANY.

Registration of all Practitioners of Medicine.

A bill carefully prepared, and approved by leading members of the profession, having this object in view, is now before the legislature of Pennsylvania. Copies of the report of the committee on Medical Legislation, read before the State society, at its last meeting, have been laid on the desks of the members of both Houses, and the following memorial, as well as petitions have been presented:—

To the Honorable, the Senate and House of Representatives of the Commonwealth of Pennsylvania, in General Assembly met:—

The undersigned memorialists, being the officers, the permanent members and the delegates, at the last meeting of the Medical Society of Pennsylvania, respectfully represent that the Act approved March 24th, 1877, entitled "An Act to protect the people of the Commonwealth against incompetent practitioners of Medicine, Surgery and Obstetrics," has failed to accomplish the important objects aimed at.

The Legislature of the State of New York, at its last session, passed an act requiring all persons who practice medicine or surgery to register in the office of the clerk of the county in which the practitioner resides. In like manner the Legislature of the State of New Jersey, at its last session, passed an act requring each practitioner to file a copy of his or her medical diploma in the office of the clerk of the county, and on failure of this to abandon the practice of medicine.

What your memorialists especially desire at present, is, that an act may be passed which shall provide for the registration of all practitioners of medicine, irrespective of the so-called schools of practice, as in all European countries, the Canadian provinces, the South American States, and in some of our own States. Experience has shown that incompetency, deception and fraud can be more easily prevented by this

means than by any other. The legal profession, after an examination, requires all its members to register under oath or affirmation, and there appears to be no good reason why provision should not be made for the medical profession in Pennsylvania.

In conclusion, your memorialists beg leave to ask your attention to the Report of the Committee on Medical Legislation, read before the Medical Society at its last meeting. And we will ever pray, etc., etc.

Information on this subject may be obtained through the chairman of the Committee,

R. L. Sibbet, *Carlisle, Pa.*

Improvement in Florida.

An important enterprise, with the object of re claiming South Florida, has been started.

The drainage of Lake Okeechobee, contracted for by the authorities of Florida, will, if successfully accomplished, result not only in the reclamation of the bed of the Lake itself, but, it is believed, in that of the two vast swamps known as the "Everglades" and the "Big Cypress," which lie south of the Lake, and cover the greater portion of the lower end of the peninsula. The "Everglades," sixty miles in length, and about the same in width, really constitute a vast lake, from one to six feet in depth, studded with thousands of small islands.

As the extreme southeastern portion of Florida has legitimate claims, as a health resort, over any portion of the State, the sanitary value of this scheme deserves the attention of physicians.

The Philadelphia Dispensary.

The secretary of this excellent institution says, in the course of a letter in the *Public Ledger*:—

"The beneficent objects of this institution in behalf of the deserving poor—to treat the sick who are curable and "to make the path to Heaven easier" for those who are not—were never better carried out than at this time. And should any Christian man or woman feel it in his heart to give or bequeath a fund of say ten to twenty thousand dollars to the Philadelphia Dispensary, the income to be awarded, according to the rules and judgment of the Board, to the physicians who toil and day and night in its service without material reward of any kind, it would be a practical recognition of their deserts greatly to be desired."

It certainly would be a most meritorious action, and we hope the secretary's words will not fall unheeded.

The Smallpox Epidemic.

This dreaded disease has assumed the proportions of an epidemic in various parts of the country. In this city the deaths are about sixty per week. In Danville, Pa., the public schools have been closed on that account. It is reported to be "making terrible ravages" in Bellechasse and Dorchester Counties, Quebec. In Chicago, ten to fifteen new cases daily were reported to the Health authorities. In the penitentiary at Fort Madison, Wis., contract work is abandoned, on account of the number of cases in the institution. Jefferson, Dakota, has been surrounded with a "shot gun" quarantine; out of ninety cases thirty-two were fatal. The railroad authorities forbid trains to stop there.

These are only a few of the numerous items of the kind in the daily papers.

Cremation in Rome.

A warm discussion took place recently, in the Municipal Council, relative to the official recognition of cremation. A petition had been received from the Society for promoting this method of disposal of the dead, asking permission to erect a furnace and other necessary appliances in the public cemetery. A good deal of sentiment was, of course, imported into the matter by several speakers, but finally, chiefly owing to the clear and temperate address of Dr. Baccelli, the motion to grant the request was carried by a substantial majority. Cremation, therefore, is now legalized at Rome, as at Milan, Florence, and other towns.

Humanized Vaccine Virus.

At the request of various correspondents, we have arranged to supply those who wish it with humanized vaccine virus, in the shape of scabs. They are obtained from healthy white children, and are guaranteed fresh and active. Price $1.50 and $2.00, according to size.

The deaths from smallpox in this city numbered, last week, 61, a decided increase on the average of the last month.

Trichinæ in a Cat.

Living trichinæ, says the *Pathologist*, have been recently found, at the pathological laboratory of the Long Island College Hospital, in the muscles of a cat which had "died from natural causes" and been brought to the laboratory for dissection. The animal was emaciated and icteric. Placed on a slide, in a neutral solution, the trichinæ kept up a spiral, vermicular movement for several hours.

Confessions.

A correspondent writes: Your new departure in inviting the profession to publish errors as well as successes is a capital idea, and it is to be hoped that it will elicit many responses. If it does not, it will not be owing to the scarcity of the article. I have a dim recollection of having committed one or two myself, "in the early years of my practice," as the fathers say.

Items.

—Positively the last of General Washington's servants died last month, in Washington. This was Sally Hunter, who was one of the slaves manumitted in his will. She was born—so it is said—on his estate, in 1766, and hence was 115 years old. It is about time for these famous freedmen to become extinct.

—The annual report of the Board of Health of Chicago shows that there were 10,462 deaths in that city during 1880, out of a population of 503,298. This shows a death rate of 20.79 per 1000.

—There was a man in Indiana who paid a highly promising oculist $10 for so treating his eye that he could see as well by night as by day. The operation was perfectly successful, for now the man cannot see at all.

—The New York Board of Health has passed an ordinance making it a misdemeanor, punishable by a fine of $25, to hold public or church funeral services over any person who dies from a contagious or infectious disease, such as smallpox, diphtheria, scarlet fever, yellow fever, typhus fever, or Asiatic cholera.

—Dr. Octave Pavy, the Gulnare's surgeon, who remained in Greenland with Henry Clay, of Louisville, when the Gulnare returned home last fall, writes that he intends to go north by water next summer, to deposit provisions at different points, intending to start north with dogs and sledges the winter after, and he is hopeful that he may reach a high enough latitude to settle the question of an open polar sea.

OBITUARY NOTICES.

—Dr. George Taylor, of New Milford, Conn., died recently, aged 79 years. He was the oldest homœopathic practitioner in the State, and the first, in 1837, to introduce the doctrines of Hahnemann. He graduated at the Yale Medical School in 1824.

—Dr. Samuel T. Knight, a well known physician, died Wednesday night, Jan. 19, at his residence, No. 112 North Greene street, Baltimore, in his sixty-fourth year. He was a practicing physician in that city for over 40 years. He served one term and part of another as Health Commissioner.

—Dr. George Ferrel, member of the West Virginia House of Delegates from Berkeley County, dropped dead at his boarding-house in Wheeling, Feb. 2. He was in the House on Monday, and was taken slightly ill just before adjournment, but nothing serious was apprehended. His disease was announced as spinal apoplexy.

—Dr. Charles Winterburn died in New York last week. He was born in Yorkshire, England, 65 years and 9 months ago. He came to this country in 1840, and went to Cincinnati, where he practiced medicine till 1865. He then removed to New York, and followed his profession until his death on Sunday morning, January 20. He was found dead in bed, when called for breakfast, having died of paralysis of the heart.

—George W. Hewitt, M.D., died at his residence, in Franklin Grove, Lee Co., Ills., Wednesday evening, January 12th, aged 50 years. He was born in Middleburg, Franklin Co., Pa. His medical studies were pursued under Dr. Samuel Chew, of Baltimore, and at the same time he attended lectures at the University of Maryland, where he graduated in 1854. On the first of May of the same year he located at Franklin Grove, and pursued the practice of medicine until within a few months of his death. During the late war he served as Brigadier Surgeon under General Kirk. He was an active member of the American Medical Association, and attended many of its meetings. He was a member of the Masonic fraternity, and was buried under the auspices of Dixon Commandery, No. 21, on Sunday, January 16, 1881.

QUERIES AND REPLIES.

Dr. R. B. G, of Tenn.—The best work on Dietetics for children is, probably, "Jacobi's Infant Diet," price 75 cents.

Dr W. E. H., of Pa.—A microscope good enough for all ordinary clinical purposes, can be bought for $40 or $50.

Dr. Michel.—1. There is no unanimity of opinion among the physicians of this city, as to the relation of typhoid fever to sewer gases. 2. The mortality of the disease is supposed to be about 14 per cent. 3. The cold bath treatment is not in vogue here.

Dr. S. K, of Ga.—We are not aware of any cases of tapeworm having been supposed to have been derived from extracts of beef. The thing is not impossible, but is certainly unlikely.

Pharmacist, Pa.—The subject of the relations of pharmacists to physicians is just now being actively discussed in this city, and with a fair prospect of benefit to both parties.

MR. EDITOR.—If Dr. Laverty, of Middletown, Pa., will put his patient on fluid ext. ergot, and fluid ext. jaborandi, equal parts, and give teaspoonful doses three or four times daily, I think he will reduce the quantity of urine rapidly, and excite a proper action on the skin. He can reduce the quantity of jaborandi, and increase the ergot, if circumstances require. Should he use it, let us hear the result. J. M. KELLER.

Hot Springs, Ark., January 22, 1881.

MARRIAGES.

ASHENFELTER—ROYER.—On Jan., 20, 1881, by the Rev. C. W. Schaeffer, D.D., at the residence of the bride's father, W. G. Ashenfelter, M.D., of Pottstown, Pa., and Isabella, daughter of State Senator Lewis Royer, of Trappe, Pa.

LOVEJOY—DUNTON.—In Germantown, Pa., on the 19th inst., by the Rev. W. J. Chichester, assisted by the Rev. S. C. Hill, Rev. W. W. Lovejoy, M.D., of Boston, and Miss Emma Dunton, of Germantown.

DEATHS.

ARROTT.—In this city, on the 24th inst., Dr. Colin Arrott, in the seventieth year of his age.

BUGBEE.—In Waterford, Vt., Jan. 11, Dr. Ralph Bugbee, in his 85th year.

DARRACH.—At Germantown, Pa., on Friday evening, January 28, William Darrach, M.D.

LIPPINCOTT.—At Salem, N. J., on Seventh-day morning, the 22d inst., Dr. A. B. Lippincott.

PARSONS.—In this city, suddenly, on the 21st inst., of paralysis, Dr. John B. Parsons, aged 45 years

RAMSEY.—In this city, suddenly, on the 27th inst., A. M. Ramsey, M.D., in his 36th year.

WINTERBURN.—In New York, suddenly, Sunday morning, January 23, 1881, Charles Winterburn, M.D., formerly of Yorkshire, England.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat. according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O	
Quinidia do	15 "	20	24	2	2	
Cinchonidia do	15 "	C	H	N	O	
Cinchonia do	15 "	20	24	2		
Chinoidine Purified,	30 "					

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

NASAL, POST-NASAL, SUPRA-POST-NASAL AND PHARYNGEAL INFLAMMATIONS—CONSIDERED WITH REFERENCE TO DISEASES OF THE MIDDLE EAR; WITH REMARKS UPON TREATMENT.

BY CHAS. S. TURNBULL, M.D.,

Of Philadelphia, Pa.

Read before the Philadelphia Laryngological Society, January 28th, 1881.

The subject under consideration is one which of late years has attracted unusual attention in this as well as in other countries, taxed the skill and ingenuity of some of the most learned of medical men, furnished a luxurious living to hosts of charlatans, made countless numbers of sufferers outcasts from or nuisances to society, or else wrecked the hopes, if not the lives, of many human beings.

A neglected coryza, exposure to the weather (especially that of our Eastern States), or dust-charged atmospheres, the abuse of tobacco, hypertrophy of the tonsils, and above all, lack of hygienic education, tend to the condition of subacute or chronic nasal, post-nasal, or pharyngeal inflammations. Such subacute inflammations may be associated with congestion, hypertrophy, sclerosis, or ulceration of the Schneiderian mucous membrane, the formation of polypi, tumors, etc. Chronic inflammations, on the other hand, are associated with an aggravation of the enumerated symptoms, with necrosis of tissues or bone, and cicatricial malformations. Were it not for the inviting means of ingress to the tympanum, through its appendix, the Eustachian tube, deafness would be a rare condition, since, after an experience extending over more than ten years, we would most unhesitatingly state that at least *two-thirds* of the cases which have come under our notice have been due to extension to the tympanum, through the Eustachian tube, of post-nasal, *supra-post-nasal* and pharyngeal inflammations. We have in this connection purposely avoided the word "catarrh," which we consider ambiguous, not only as used among medical men, but also as received by the laity. It is an accepted term for most inflammations of the mucous membranes throughout the body otherwise unaccounted for. It is a bad name, unless thoroughly understood, and to be condemned, because the laity are invariably terrified by its mention, especially when used with reference to the naso-pharynx or middle ear. Hence its peculiar value to the alarmist and to the charlatan.

"Have I the catarrh?" asks the agitated patient, through whose mind flashes the thoughts of ostracism from society. A disgusting object is immediately pictured, with discharging nostrils and fauces, fetid breath, disfigured countenance and nasal articulation; always "hawking," spitting or blowing out a miserable existence. Such, we assure you, gentlemen, are, in our experience, exactly the thoughts which occur to the minds of the majority of laymen who hear for the first time the word "catarrh" applied to their complaint, and it matters little with what other words soever it be coupled. To the public mind "catarrh" has but one signification, *i. e.*, of a loathsome disease of the head, and it therefore strikes terror to the minds of

those to whom it is applied. Flaming newspaper and almanac advertisements are recalled, where it has been read "catarrh leads to consumption, to bronchitis, to falling in of the nose, to loss of voice, destruction of personal appearance, disease of the brain, etc., etc." We strongly object to the word "catarrhal," and on every occasion endeavor to avoid its use, which, we note, has of late become as common as is the term "neuralgic," which is applied to every variety of pain otherwise unaccounted for.

That every variety of nasal and post-nasal inflammation may be characterized by some peculiar and attendant condition, we are sure no member of this Society will deny, and we much prefer the use of such distinguishing terms as *acute*, *subacute* or *chronic*, hyperæmic, hypertrophic, membranous, mechanical (from dust or foreign bodies), sclerosed, endemic, epidemic, ulcerous, necrotic (ozena), polypoid, gelatino polypoid (sac-like), adenoid, etc., *inflammations* of the *nares*, *post-nares*, *supra-post-nares*, etc. Of this last named form we would speak somewhat at length, but not in especial connection with tympanal disease.

One cause of middle ear (tympanal) disease is, as experience has taught us, due to the fact that many persons actually do not know how to blow their noses. This remark may seem ludicrous, but it is nevertheless true. There is a wrong as well as a right way of blowing the nose, to free it from the secretions of its mucous membranes. One man sniffles, because his surroundings are such that he has no chance to free his nose, and the mucus becomes more and more tenacious, until, at last, he rushes off to be alone, and forcibly unloads the nostrils, at the same time inflating the ears at each blow. Another is too indifferent to blow his nose, and in attempting to breathe through his nostrils, with his mouth closed, draws the mass of tenacious mucus backward into the mouth, and once having started the collection, must "hawk," and snort, and perhaps gag, until the nares are cleared, or perchance, his own or somebody else's last meal be lost. Drawing the mucus through the nose and backward into the mouth, once commenced, is a most dangerous procedure. Indulged in, it is a most pernicious, disgusting and dangerous habit, and one which seems to grow with the American people, for it is impossible to ride any distance, now-a-days, in a street car, without being treated, no matter how many be riding therein, to a sound and a sight more disgusting to us than the effluvia of the meanest of dissecting rooms. Some persons *never* use a handkerchief; they seem to prefer clearing the nose by way of the mouth; in such, the anterior portions of the nostrils always become dry; usually rendered all the more irritable by the habit of picking away dried pieces of mucus, or forcibly cleansing with the handkerchief over the finger.

We vigorously discourage the vile habit of "hawking," and have found it *can be overcome* by resolute and methodical persons, who will carefully cleanse the parts and blow their noses scientifically, and although we have gone somewhat into detail, can most assuredly state that it is attention to details in the treatment of chronic post nasal, or post-nasal and associated middle ear, inflammations which insures success.

Then, too, the uvula is, by the powerful suction efforts to dislodge inspissated mucus, irritated, inflamed, and elongated. *Each "hawk" or effort to expel mucus helps make the uvula longer, and our most positive convictions are that elongated uvulas are usually mechanically produced in this way*, and are found associated with chronic post-nasal and supra-post-nasal inflammations, and the greater the "hawker," the longer the uvula.

So, too, in the case of what we have called *supra-post-nasal* chronic inflammations, which are characterized by the existence of a "*button*" (as patients invariably describe it) of mucus, which dries, shrinks and irritates the *superior portion of the posterior wall, or the vault of the pharynx;* too high up, almost, to be seen with the rhinoscopic mirror. This condition, too, tends to elongate the uvula, and occurs more frequently in females, and especially singers.

This particularly annoying form we would describe as a variety of local inflammation, high up on the posterior wall, or else the roof, of the pharynx, upon which settles a mass or it may be masses of jelly or glue-like, tenacious mucus, which, being dried by the air, often by artificially heated (furnace) air, shrinks and drawing upon the inflamed, or it may be, ulcerated mucous membrane, produces the sense of fullness of the fauces, and causes "hawking" and forcible attempts at removal. Each time this "button" comes away, it may be daily or only weekly, a sense of relief is experienced, but an abraded or ulcerated spot is left, upon which the "button" will re-form; but not until it begins to dry does it cause irritation by its presence. Such "buttons," when drying, are usually the cause of a fetid breath, and their presence is invariably the cause of solicitous complaint on the part of our patients, who, even themselves, are thus made

aware of the existence of these curious formations. Forcible removal of these "buttons" by means of the moist sponge held in the Eustachian forceps, and by the aid of the mirror, causes pain (lasting for twenty-four hours) or hemorrhage, and tends to make matters worse. They should be soaked, by washing with a "U"-shaped glass tube, or as otherwise directed, when we come to speak of treatment, every two hours, and when dislodged, the seat of such collections dusted daily, with pulverized tannin, grs.xv., thymol, grs.iij, (*to cover the odor of*) iodoform grs. v., or applied by a soft sponge. If ulceration exists, a strong solution of the powder just mentioned, in glycerine, or even carbolic acid or nitrate of silver in solution, may be used by a dexterous operator. We do not, as a rule, care to take the risks of dropping caustic solutions upon the vocal cords, or into the trachea, and when using nitrate of silver, *as a last resort*, prefer having it solid, as melted upon the end of a silver probe. We have not used nitrate of silver, except now and then locally and in the solid form, for the past three years, and cannot express any liking for it as a local therapeutic agent, but much prefer carbolic acid in the treatment of nose, throat, or ear diseases.

We invariably instruct our patients who are suffering from the combined effects of associated post nasal and tympanal disease in the art of blowing their noses. Little children cannot be taught too soon how to blo v their noses, and some intelligent person should assist them in so doing; because, should they suffer at any time before boyhood or girlhood from an acute, or even chronic inflammation of the Eustachian tube and middle ear, the aural surgeon is almost powerless in attempting the inflation of the same with the air douche. It cannot be successfully performed in children under five years of age, but it can be done even by the mother or nurse, when once they are taught, by suddenly compressing the nostrils, as the child *attempts to blow its nose.* It may also be done by blowing forcibly through a stiff gum tube held in one nostril of the crying child.

In connection with post-nasal middle ear disease, we consider the pocket-handkerchief a much abused, although necessary, article of apparel. The handkerchief should be firmly held against one side of the nose and bagged around the orifice of the other nostril, so that there may not be the slightest resistance to the escape of mucus. Otherwise, the operation of Valsalva, or that of inflating the middle ear, is performed with every blow. Hence, forcible blowing of the nose is to be avoided, as, also, the bending forward, at the same time, of the head, because the latter position tends to cause inflation of the tympanum.

We have mentioned the *abuse of tobacco* as a cause of post-nasal and middle-ear disease, but would wish to be thoroughly understood upon this important subject. When suspecting the abuse of tobacco, we question our patients closely concerning the methods of using the same, and impose restrictions. We are of the opinion that its sudden withdrawal tends, in many cases, to do as much harm as good. Dyspepsia and its accompanying train of evils invariably follow the sudden withdrawal of such a salivary stimulant, especially in persons past middle age. Except in the cases of young persons (say under twenty-one), we have never seen the moderate use of good cigars do any harm; on the contrary, it has done good, especially in persons of sedentary habits. While not desirous of placing ourselves on record as advocating the use of tobacco, we would state that *we consider one good cigar, smoked immediately after each meal, and without a holder, providing there be no expectoration caused, and the smoker avoid draughts of air, and sit quietly in or out of doors, as entirely innocuous and usually beneficial. We invariably advise smokers who must expectorate to give up the habit at once.* Smoking while walking, *driving* or sitting in a draught, causes expectoration, and hence is injurious, as also are pipes, cigar and cigarette-holders and stumps, which become rank; they, too, cause expectoration. post-nasal inflammation hawking, etc., or the swallowing of more or less concentrated tobacco juice. Cigarettes are hurtful on account of the fumes of the paper, and cause, when the smoke is blown through the nose, sclerosis of nasal and pharyngeal mucous membranes, chronic laryngitis, etc., so does also smoking when *driving* in an open vehicle. Pipes are seductive and unclean, by not only consuming large quantities of tobacco, but soiling the hands and garments, while the smoke is heated and the suction efforts tend to congest the naso-pharyngeal mucous membrane. All of the cases of tubal or tympanal disease which we have attributed to the abuse of tobacco have had their origin in chronic inflammation of the post-nasal and pharyngeal space, in those who expectorated while smoking, or who used many bad cigars, or smoked the same while walking or driving. In such, the pharyngeal wall is always dry and sclerosed, and the sense of taste, as well as of smell, is often impaired. We do not say "stop smoking," but while imposing conditions, permit indulgence in the lux-

ury, which, like most blessings, is often abused. We have experienced great pleasure in having our opinions sustained by old and experienced smokers; in having those who abuse tobacco acknowledge the cause to be one or the other which we have mentioned; and what is most conclusive evidence, many materially improve in health and hearing under a proper moderate use of the weed.

Enlargement of the tonsils is another cause of post-nasal, tubal and tympanal inflammation. Such enlarged glands act mechanically by causing extension of inflammation, rarely by making pressure upon the mouths of the Eustachian tubes, but by closing the post-nasal space. By testing the hearing with the mouth at first closed and then wide open, enlarged tonsils, suspected as a cause of deafness, will be drawn forward or away from the mouths of the tubes and the hearing will improve. In excising enlarged tonsils we prefer the long scissor-forceps, with teeth on one side (Fig. 1), and the knife of Yearsley (Fig. 2), having a short, rounded blade, set at an angle to the handle. Or, for children, the tonsillotome of Mackenzie.

Fig. 1.

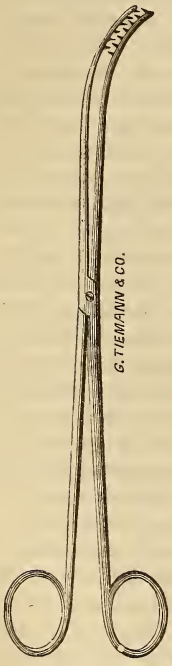

Fig. 2.

As regards the tediousness attendant upon the treatment of all forms of post-nasal inflammations, whether associated with aural disease or not, we will be sufficiently well borne out by the members of this Society, that unless the surgeon as well as his patient be well stocked with patience, treatment will be of little avail.

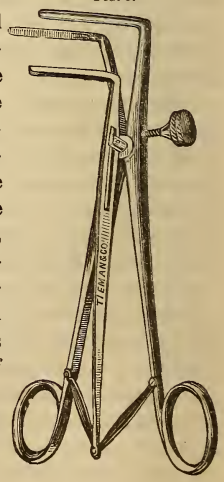
We have directed especial attention to what we consider the causes and nature, as well as the treatment, of post-nasal, etc., inflammations, since they are, through tubal transmission, the most fruitful sources of middle ear disease. It is the chronic, hypertrophic, sclerosed, or especially exudative forms of inflammation of the post-nasal space, in which the mucus collects and dries, or is drawn or else falls into the throat and mouth, which are the most frequent causes, by extension of tubal and tympanal inflammations, and consequent "throat deafness."

Before proceeding to a description of the forms of middle-ear disease, of throat, *i.e.* post-nasal, origin, we would refer to the methods employed to remove the cause of such tubal or tympanal diseases, a proper understanding of which is of vital importance in their successful treatment. As regards the treatment, we would repeat: Remove the cause. Some one may ask, "How shall our patients avoid atmospheric changes?" Teach them to keep their mouths shut and breathe through their noses, whether asleep or awake, indoors or out of doors. Licorice, clear sugar candy, "jujube paste," or gum-arabic should be kept about the person, and in going out into the cold or coming into warm apartments from the street, a piece of one or the other substance should be placed upon the tongue, since in sucking the same the mouth *must* be kept closed. They should avoid places of amusement, etc.; cars (street and steam); badly ventilated or over heated apartments, etc. Have sufficient air in sleeping apartments and heat with the bed clothes. Endeavor to fall asleep with the mouth closed, or even, as we have seen successfully practiced, tie up the lower jaw upon retiring. Of course, if our patients be wealthy, we send them South, to a more genial climate.

The majority of our most intelligent patients are treated for a certain length of time, after which they are placed under their own care. Such are seen now and then, and are taught the methods we prefer, and encouraged to be diligent in the plans we are about to describe.

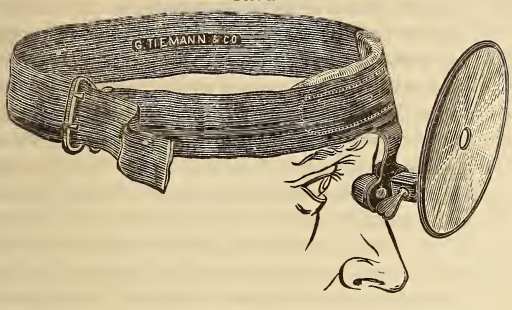
Had we omitted every other instrument, and mentioned only the rhinoscope, we would have named the most valuable in the treatment of post-nasal as well as middle-ear diseases. In fact, the post-nares could not be examined satisfactorily, much less treated, without the aid of the rhinoscope. As for the nasal douche of Thudichum's fame, in the treatment of *chronic post-nasal or supra-post-nasal* "catarrhal" inflammations, you might as well let it play out of the window as expect to benefit one such case by its use.

Fig. 3.



Having inspected the nares with Elsberg's nasal speculum (Fig. 3), or the external auditory meatus and membrana-tympani, as the case may be, we at once have resort to Shrötter's forehead mirror (Fig. 4), or rhinoscopic mirrors, and examine the post- or supra-post-nasal space, and faucial orifices of the Eustachian tubes, and in the majority of cases arrive at once at a satisfactory diagnosis. If the case be one in which the patency of the Eustachian tubes is to be determined, we employ the otoscope, or auscultation tube, Valsalva's experiment, or forcible inflation with Politzer's air douche. The vapor of chloroform or of hydrobromic ether is more penetrating than atmospheric air in employing Politzer's method, and we have often inflated the tympanum by this means when all others had failed. A relaxed condition of the fauces, especially such as is found in the case of anæmic or old persons (particularly when the teeth have been lost and the alveolar processes absorbed), tends to collapse of the walls of the tube. This condition cannot be diagnosed from the condition of complete stenosis, except by the use of some such penetrating vapor as we have named. To mention sulphuric ether is only to condemn it, because its odor is absolutely disgusting to the majority of persons.

Fig. 4.



In the treatment of nasal and post-nasal inflammations, we consider cleanliness and the methods proposed for accomplishing the same as of the greatest moment. If the mucus accumulates and flows, or collects and dries posteriorly we direct the cleansing fluids in that direction, but if the secretions be discharged anteriorly we direct the cleansing fluid from the fauces forward. In most cases we use warm, weak, carbolized solutions of chloride of sodium, one half to two pints to each side. Chlorate of potash, sulphate of zinc, carbolic acid, tincture of iodine, glycerole of tannin, etc., are used in varying proportions, the strength of the solutions being determined by the exigencies of the case, but never exceeding one half the strength of ordinary gargles.

The first cleansing must be conducted by the physician, if only to teach the patient how to continue the tedious process and guard against injury of the Eustachian tube or tympanum.

To cleanse the nares, or post-nares, through the nostrils, we are most particular. We use either the hand, a straight tube (as a pipette), or, better, a "**U**"-shaped glass tube with a flanged opening at one end and a bulbar nozzle at the other, directing our patient to close one nostril with one hand, and snuff, or draw forcibly from the other hand or from the tube, *at the same time throwing the head as far back as possible.*

We consider most reprehensible the indiscriminate advice so generally and thoughtlessly given, "snuff salt and water up your nose." In so doing the frontal sinuses become filled, frontal and often most severe headache and chronic inflammation (often mistaken for "supra-orbital neuralgia") ensue, and the patient is frightened from making more than the first attempt. By our method we have never had headache complained of, and the wash impinges more directly and forcibly against the supra and post-pharyngeal wall, the most frequent seat of inspissated and desiccated mucus. The parts are to be cleansed twice daily, and the nostrils subsequently blown out, as already directed. After the evening washing out, and immediately before retiring, vaseline, or better, cosmoline, a piece the size of a pea, is to be drawn part way up into each nostril, there to be retained, and allowed to melt and soften the masses of dried mucus. If there should exist a strumous diathesis, or specific taint, we use one grain of the yellow oxide of mercury to each drachm of cosmoline, or if there be smarting or pain in any instance, we add one-half a grain of the muriate of morphia to the ointment. If the patient be subjected to a dust-charged atmosphere, and the anterior portion of the nose be inflamed, or ulcerated, as is usual in the cases of weavers, wood and stone workers, upholsterers, cigar-makers, etc., we order the nostrils to be anointed, three times daily. Before each fresh application the preceding one, with the dust it has collected, is to be wiped off with a soft, dry cloth. If the post-nares are likewise mechanically irritated, we order light pledgets of wool to be worn in the nostrils or a protective snuff, composed of equal parts of powdered gum-arabic, bismuth carbonate and lycopodium, which is to be used throughout the day, washed out nightly by the process above described, and the parts well anointed. For washing out the nose and fauces, from behind, we

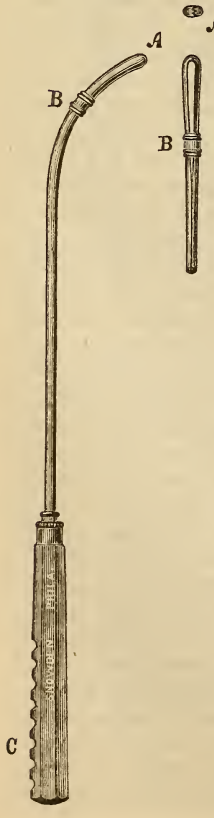
Fig. 5.

prefer the hard-rubber post-nasal syringe (Fig. 5), or use one of the several forms of spray producers, or the fan-shaped jet apparatus of Dr. J. S. Cohen, to which we have added other nozzles (Fig. 6).

Fig. 6.

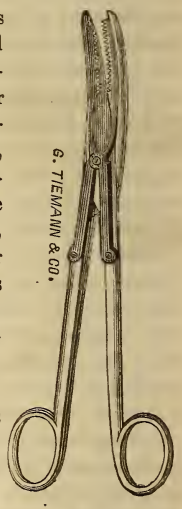
Also as culpable do we deem the advice, "use the nasal douche." Except in cases of ozena, or specific ozena, where it is absolutely indispensable, we particularly avoid and discourage the use, except in the surgeon's own hands, of all forms of nasal douches. So, also, any other form of spray or forcible jet-producing apparatus, so often allowed in the hands of the patient, because in the cases of tubal or tympanal complications, or where the faucial orifices of the tubes are patulous, the solutions used are sure to enter the middle ear and do harm. We have had cleansing solutions enter the tympanum while carefully using the post-nasal syringe for our patients, and consider we cannot be too careful in the employment of the same.

Fig. 7.



All masses of mucus, growths, etc., to be removed, as also applications to the pharynx, its vault, the post nares, or the Eustachian tube orifices, should be carefully performed by the aid of the rhinoscopic mirror, exactly as in the case of the larynx. In making applications to the parts under consideration, we use fresh pieces of sponge, held by the Eustachian forceps (Fig. 7) devised by my father, Laurence Turnbull, M.D. By taking the cases under our personal observation and manipulation, we have had most encouraging success, and with rare exceptions, have found it quite unnecessary to use any form of surgical interference, such as that for the removal of hypertrophied mucous membrane, or even new bone formations. In this connection we might refer to the operation for the removal of elongated uvulas, because having once become so, they excite faucial irritation and induce a continuance of the very trouble which in the first place has led to their formation. We have met with them of varying shapes and lengths, some tapering to a point, some club-shaped, some spatula-shaped, others curled, as it were, to one side or the other, and from one-half to three inches in length. In one case, the extremity of an elongated uvula was glued to the posterior wall of the pharynx. We prefer the scissors (Fig. 8) with teeth combined on the inferior (concave) surface of the blades, to all other forms of instruments for abbreviating the uvula, and would, in no case, cut closer than one-fourth of an inch from the base. We use broken ice, sucked for some minutes prior to and some fifteen minutes subsequent to the operation, *and invariably direct half-hourly, or still more frequent, garglings of warm salt water*, because, as a rule, the process of cicatrization in such cases is both slow and painful. Condylomata hanging from the soft palate are inviting to the use of the scissors, but we have found by experience that such disappear sooner when unirritated and treated specifically.

Fig. 8.

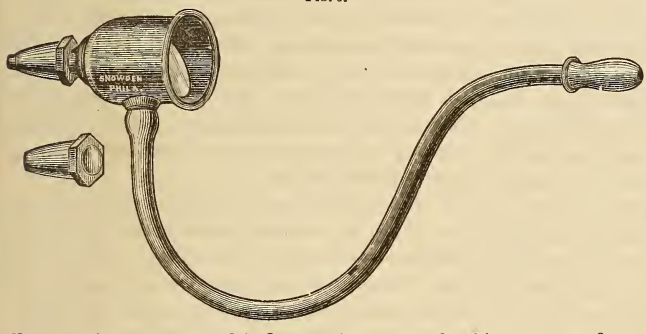


Invasion of either the Eustachian tubes or the middle ears, by extension of any inflammatory process may be readily controlled if taken in the onset of the attack, and vigorous treatment of the cause, coupled with careful conservative treatment of the tympanal or tubal disease, is usually crowned with success. *Once having occurred, patients are* ALWAYS *liable to have such extension of post-nasal to tympanal inflammations recur*, and caution to such can be utilized to great advantage. It is the unfortunate fact, however, that the aural surgeon is not consulted until too late, *i. e.*, when the tympanal membrane as well as the post-nasal wall disease has become

chronic. It may be that the Eustachian tubes have become strictured—perhaps permanently closed—and the tympanum a vacuum (hence tinnitus-aurium), the muco-periosteal membrane lining the tympanum hypertrophied or sclerosed, connective tissue bands stretched cob-web-like across the cavity of the middle ear, the ossicular joints anchylosed (hence tinnitus-aurium), the membrana-tympani thickened, retracted, or even held motionless; in short, the conducting acoustic apparatus almost ruined. In this class of cases there is but little, as a rule, to be hoped for beyond the retaining of a moderate amount of hearing power, which power, unless intelligently nursed and watched, will annually grow less.

In the treatment of chronic inflammations of the middle ear we seek to keep the Eustachian tubes pervious and free from collections of mucus by the use of the air-douche and stimulating vapors, but we never, on any account, use a bougie or sound; they are dangerous in the extreme. To

Fig. 9.



allay the intra-tympanal inflammations, we also use external counter-irritants over the mastoid process, exercise the ossicular joints, and with them the membrana-tympani and its muscles, by the air douche, Valsalva's experiment, or Siegle's pneumatic speculum. This instrument (Fig. 9) we have modified by covering the specular end with lead-pencil rubber, to perfectly close the meatus, create a vacuum, and prevent pain and subsequent inflammation from irritation. We inject solutions of salt or soda and water into the tympanum by means of the catheter, small syringe, and Politzer bag; and administer, for from two to three weeks, small doses of the biniodide of mercury (gr. $\frac{1}{10}$ t. d.) followed by iodide of potassium (5 grs. t. d., after meals), for a month or more. In chronic inflammations of the middle ear there is, as a rule, atrophy of the ceruminous glands, hence absence of secretion, and this fact is one of the most prominent of diagnostic symptoms. We always supply, in such cases, often with benefit to hearing, an artificial cerumen, to be used nightly, of—

℞. Muriate of morphia, gr.j
Yellow oxide of mercury, grs.ij
Cosmoline, ℥ ij. M.
Make an ointment.

Sig.—Use every night, to anoint the ears.

We have used the vapor of hydrobromic ether (Wyeth's) with marked success, and prefer it when there is narrowing of the Eustachian tubes or tinnitus aurium of a congestive character. The forms of tinnitus aurium accompanying middle ear inflammations vary, as do all symptoms of any disease, but are usually of a singing or hissing character, and are entirely dependent upon the conditions existing within the tympanum.

We have adopted the general rule, that after having removed the cause of any chronic middle ear inflammation, and treated our patients for several weeks without any signs of improvement, and having satisfied ourselves that the hearing is not becoming worse, we educate them in the proper care of their cases, discourage hopes of a return to complete recovery, and encourage patience and care in order that they may retain what hearing they have. We never advise our patients to attempt the use of the air douche (Politzer's) at home, because such are invariably failures, but prefer their practicing the Valsalva operation, and using with it a vapor of—

℞. Tincture of iodine, (U. S. P.) f. ℥ j
Chloroform, f. ℥ ss. M.

Sig.—Use as a vapor to "sniff" up the nose. (Put into f. ℥ j ground-stoppered bottle, half full of absorbent cotton.)

to be forced into their middle ears. Before using this, however, they must know exactly how to inflate the ears, and be taught not to inhale the vapor, but "sniff" it up the nostril, and by compressing the nostrils and making a short, quick (Valsalva) effort, force it into the tympanum. This procedure we have found of especial benefit in cases where patients have been unable, from any cause, to receive treatment at our hands, and in proportion to their intelligence and perseverance has it proved successful.

In this somewhat lengthy summary, but far from detailed account of the subject under consideration, we have, gentlemen, while perhaps taxing your patience, endeavored to state our experience and the methods and plans of treat-

ment we have adopted, and, in conclusion, would add that no special branch of medicine or surgery offers a more extended field for original investigation and manipulation.

FACTS FROM THE SMALLPOX HOSPITAL AT TROY, N. Y.*

BY CLARKSON C. SCHUYLER, M.D.,
Asst. Surgeon, Troy Hospital.

What I have to offer is merely a *résumé* of a service of four months at the smallpox hospital in Troy. As every phase of the disease was noted, and some unusual phenomena observed, I have thought that this recapitulation might not be uninteresting, inasmuch as the disease still prevails, and some of you, I understand, have it in your midst. While, as will be inferred from what I have said, I do not propose to make this a treatise on smallpox, I would like, however, to call your attention to what are to me some interesting facts in the etiology and symptomatology of the disease of which I took cognizance.

While there is little doubt that the greatest danger from infection in this disease is during the stage of suppuration and desiccation, I am led to believe, from the history of cases noted in families where its members have successively contracted the disease, that there is no stage in which it cannot be communicated; that the breath and exhalations from the body during that part of the period of incubation immediately preceding the stage of invasion can infect the unprotected. These views, while they are contrary to general belief, confirm the observations of Prof. Lomas, who says: "There are well authenticated cases which prove to us that infection may take place during any stage of the disease, even during the period of incubation." I believe, however, that the danger from exposure during the stage of incubation, invasion, and the appearance of the eruption, is slight, if the patient be in a large and airy apartment.

It is well known that rarely does an individual suffer from a second attack of the disease. I have seen, I think, three exceptions, there being room for doubt in but one, in which case no evidence of a previous attack could be found upon the body. The history, however, given by the mother of the girl (whose age was 16), seemed to warrant the belief. She said that when about four years of age she contracted the disease from her father; that she was nursed in the room with the father as soon as the disease manifested itself, which was during the period of desiccation. The other cases, both men, aged respectively 36 and 37, were scarred. The former died of the *hemorrhagic* form of variola. It is a fact worthy of note that in each of these three instances the primary attack was previous to puberty. I say worthy of note, because many believe that if the protective power of vaccination during infancy is ever lost, it is at this period in life.

The precursory signs, excepting, of course, the fever, were in some cases wanting, the pronounced headache and backache, which are as a rule present, having been wholly absent. It was also observed that when the eruption did not appear until the fourth day it was invariably *discrete*. In the discrete form it was often difficult to find umbilicated vesicles at any stage of the disease. (In diagnosis this might be a source of error if smallpox were not prevailing.)

In many instances I had noticed upon the forehead and breast, in this variety, a few aborted vesicles (I refer to cases admitted on the third or fourth day of the disease, or after the appearance of the eruption). This question immediately presented itself: Did these isolated vesicles come in sight, umbilicate and abort previous to the appearance of the general eruption? I was soon able, in two instances at least, to answer this question in the affirmative.

I was called to see a young woman who was thought to be suffering from a severe cold. This was the second day of the attack. She had had the violent prodromic symptoms of variola, and it was immediately suspected that she was suffering from that disease. Upon close inspection three small umbilicated vesicles were found; one upon the forehead, one at the angle of the lower jaw, and one on the neck. *Forty-eight hours after* the general eruption appeared.

Again, I saw, with a brother physician, an old gentleman, on the morning of the third day of his sickness. He had no marked headache or backache; temperature 103½°, pulse quick, tongue dry, kidneys excreting but little. A few umbilicated vesicles were found upon the forehead, one or two of which were slightly crusted. The eruption made its appearance twenty-four hours later. Whether this is usual I am not prepared to say. I am not aware, however, that it has ever been observed. Bartholow, in his work on "Practice of Medicine," refers to a form of eruption appearing in clusters or patches, which he terms "*corymbic.*" But one case having this variety of eruption was seen. Only a single cluster, the size of a silver dollar, appeared upon the face, upon the left cheek. There were a few isolated vesicles,

*A paper read before the Union Medical Association, at Eagle Bridge, N. Y.

however, at the margin of the hair, on the forehead. A number of patches were present upon the legs and arms, the skin between them being wholly destitute of eruption for a distance, in some places, of at least twelve inches. The vesicles in some of the clusters were coherent, or in immediate contact, without being really *confluent.*

Death was inevitable, as a rule, in the hemorrhagic variety, or what is popularly known as "black smallpox." Death usually took place before the period of pustulation was reached. In those that died, not only were the vesicles filled with bloody serum, but there were extravasations of blood beneath the cutaneous layers, and hemorrhages from the various orifices of the body. I have seen them die as early as the third day. Two adults recovered, one of which suffered from abscesses for a month after.

Two cases were admitted during pregnancy, five and six months, respectively: one *hemorrhagic* the other *discrete.* The former aborted on the fourth day and died on the fifth; the latter made a good recovery, without death to the fœtus.

The pharyngitis in some cases was so severe as to render deglutition impossible. As this usually occurred during salivation, the condition of the patient was most distressing. An authority on smallpox, speaking of confluent variolæ, says: "While the eruption may be completely confluent on the face and hands, on other parts of the body it remains distinct, and never becomes confluent except over limited spaces." In two cases the eruption was confluent *on every part of the body*—one, a young woman aged 20, the other a girl of 15. The former died on the tenth day of the disease, the latter on the ninth.

The performance of laryngotomy in one case apparently suffering from œdema of glottis was seriously thought of; the patient recovered, however. No diphtheritic membrane was observed in these cases, nor in the hemorrhagic form, as is spoken of by some authorities. No uncontrollable vomiting or diarrhœa was met with. These concomitants of the period of invasion were rarely seen thereafter.

And now, as to treatment. The question naturally presents itself, Do we possess any power to arrest the development or mitigate the severity of this disease? As to the development, I answer no; excepting, of course, vaccination immediately after exposure, which, if successful, will insure a modified form of the disease. There are certain stages, the severity of which may be mitigated, especially that of invasion, with restlessness and high temperature, when aconite, given hourly, has a most happy effect. Bitartrate of potash, in the proportion of an ounce to a pint of water, taken *ad libitum*, was a grateful drink. It seemed to limit the inflammation of the skin and hasten desiccation. At any rate, those taking it "cleaned off quicker."

In severe cases you are compelled to resort to the use of stimulants, heroically, too, sometimes. Many a life has, I believe, been saved by the judicious use of stimulants at the period of suppuration, when the patient is found with a dry tongue, quick pulse, blue lips, and, sometimes, active delirium—a condition very like the last stages of typhoid. Frequent sponging during the development of the eruption was found to be very grateful.

Nothing I found gave so much comfort during the stage of desiccation as a warm bath, the patient frequently begging to have it repeated. As an instance showing the benefit derived from the baths, I may mention the case of a young man who was brought to the hospital on the sixteenth day of the disease. He was a most frightful object as he lay there before me, with hardly the semblance of a human being, unconscious and in a muttering delirium. As a *dernier ressort*, a warm bath and stimulants were ordered. In three-quarters of an hour he was removed, placed in bed and freely oiled. Within one hour he was conscious and able to tell of the suffering and neglect he had undergone previous to admission. Nothing, I believe, can be relied upon when we deal with the hemorrhagic variety; although tinct. chloride iron with turpentine seemed to be given with good effect in the two cases that recovered.

Vomiting was invariably controlled with subnitrate of bismuth, taken dry, in 10 or 15 grain doses. What was done to prevent pitting? you are no doubt ready to ask. Well, nothing, because I believe nothing can be done. The pitting depends entirely upon the depth of the slough under each pustule. If the infiltration of the pus cells into the vesicle takes place without extension of inflammation into the cellular tissue beneath, then there will be no pitting; but if it does extend into the deeper tissues and a slough is the result, then pitting is inevitable.

That some are scarred more than others is a natural course of the disease.

The whole number of cases treated was 216. I have a record of 199. As to those who died previous to my keeping a complete record, a memorandum, as to age, vaccination and variety of disease, was made.

A perusal of the following table will be of interest:—

	Number.	Variety: Varioloid.	Discrete.	Hemorrhagic	Confluent.	Corymbic.	Died.
Not vaccinated	105	7	50	12	35	1	33
Vaccinated after exposure	2	2	...	...	...	..	...
Vaccinated in infancy	64	21	24	8	11	..	10
Vaccinated	17	11	5	..	1	..	2
Inoculated	8	3	2	2	...	..	1
Had smallpox	3	...	2	1	...	..	1

Ages.	Number.	Deaths.	Percentage of Death.
Infants	11	5	45.5
1 to 10 years	68	15	22.0
10 to 20 years	44	12	27.2
20 to 30 years	46	8	17.4
30 to 40 years	18	5	27.7
40 to 50 years	8	1	12.5
50 to 60 years	4	1	25.0
Total	199	47	

It will be observed that the mortality was about 22 per cent., which we think is a very good showing, taking into consideration the type of the disease that has prevailed. Probably at no time in the history of smallpox in Troy has the disease been so malignant. And, too, the number of cases admitted when the disease was far advanced necessarily increased the ratio of mortality, premising that the hospital care and treatment were superior to that received at home. In the "vaccinated" all children were carefully examined as to scar. I mention this, as it will be seen, from the table, eleven had varioloid, five discrete and one confluent smallpox. Believing, as I do, that vaccination is an absolute protection against *smallpox* (not varioloid), I am positive that those having the discrete and confluent forms were unprotected.

Not a single case *having a recent vaccination* was admitted during my service. One child having a recent vaccination (within two weeks), was admitted, with four others of the same family having the disease, and remained in the hospital for two months without contracting the disease.

The greatest mortality, it will be observed, was among infants, 45 per cent. dying. The lowest rate was between the ages of forty and fifty, only 12 per cent. dying.

I cannot close this paper without saying a word in commendation of the heroic fortitude, patient devotion and Christian graces of the Sisters of Charity, who voluntarily connected themselves with the institution. The success of the treatment of patients therein and the low mortality among them are due, in great measure, to the watchful care and attention of these Sisters, who have shown themselves to be real ministering angels to the afflicted.

THE TREATMENT OF CONSTIPATION BY THE SWEDISH-MOVEMENT CURE.

Remarks offered at the Meeting of the Philadelphia County Medical Society, Nov. 24th, 1880,

BY BENJAMIN LEE, A.M., M.D.,
Of Philadelphia.

In order the more readily to convey a definite idea of the principles on which the Swedish Movement Cure is based, and the mode in which these principles are carried into practical execution, I have written upon the blackboard a prescription for that *bête noire* of the profession, constipation. I recommend this mode of prescribing, as the sword which, so far at least as a large amount of chronic disease is concerned, will cut the Gordian knot of the problem with which we have been wrestling this evening, namely—the relations of the druggist to the physician—for I venture to say that no apothecary can be found who will undertake to compound a prescription like this. You will observe that each clause of the prescription contains two parts; the first is the attitude or position to be assumed by the patient in taking the movement; the second is the movement itself. I have distinguished them by drawing a line down the middle of the prescription.

PRESCRIPTION OF MOVEMENTS FOR A CASE OF OBSTINATE CONSTIPATION.

1. Heave standing,	Chest expansion, deep inspiration.
2. Half lying,	Leg flexion and extension (p. r.).
3. High ride fall sitting,	Trunk twisting (p r.)
4. Toward standing,	Thigh extension, forced (p. r).
5. High ride turn sitting,	Circular twisting with pressure upon stomach and in the lumbar region.
6. Extension standing,	Colon stroking.
7. Forehead fix, high knee astride standing,	Spine extension, forced (p. r.).
8. Side stretch standing,	Liver vibration.
9. Lying,	Abdomen kneading, pressure with vibration over solar plexus.

The attitudes being very various, their nomenclature is necessarily somewhat cumbersome, while its foreign parentage makes it awkward to our ears. Suffice it to say that each variation has reference to special groups of muscles, or certain organs.

The first movement in this prescription is a respiratory one, taken in the erect position, with the chest thrown out, and accompanied by deep inspirations; its object being to invigorate the entire system by introducing a large amount of oxygen into the blood, and by means of this pure

blood supply, to bring both muscles and nerves into a highly vitalized state, in which they will respond most readily to the stimulus of the subsequent movements.

The second is derivative, designed to relieve congestion of the abdominal organs by drawing down the blood into the lower extremities. In this, the trunk is placed at rest in a semi-recumbent posture. The letters (p. r.) will be noticed immediately after this movement. They signify that *patient resists*, the movement being made by the operator. This is, therefore, a *duplicated movement*, and the entire will of the patient being concentrated upon this effort, it is powerfully revulsive.

The third movement has two principal ends: the first, pressure upon the entire abdominal contents by the abdominal parietes, thus relieving congestion by forcing the blood out of the larger vessels; and secondly, invigorating and developing the transverse and oblique abdominal muscles, which are rarely brought into play in ordinary exertions. The attitude is such as to fix the pelvis. The arms are then crossed over the top of the head, and the extended elbows are made use of as a lever, by means of which the trunk is twisted or rotated upon its axis, the patient resisting the operator's effort.

The fourth places the abdominal muscles, especially the *recti*, strongly upon the stretch, thus inviting a copious flow of blood into their capillaries, while at the same time, by irritating the muscles about the hip and perineum, and the *psoas* and *iliacus*, it stimulates the nerves of the lumbar and pelvic plexuses.

The next consists in a rapid rotation of the entire trunk upon the pelvis, bringing all the muscles of the lower part of the trunk into play, and subjecting the pelvic viscera to alternate pressure and relief from pressure. It promotes activity in the portal circulation, and stimulates peristaltic action. It is accompanied with firm pressure upon the stomach and in the lumbar region, the former with a view of stimulating the solar plexus, and the latter the lumbar nerves.

The next movement is entirely passive, the patient standing, while the operator slowly and firmly strokes the colon in the direction of its vermicular wave; its primary object being to accelerate the passage of fecal masses and flatus through that portion of the canal, and its secondary object to stimulate its rhythmic contractions.

The seventh produces extreme erection of the spine, thus affording increased space for the abdominal organs, usually compressed by improper attitudes.

The eighth movement is the movement-cure blue pill. The patient takes such an attitude as shall place the muscles of the right side strongly on the stretch, and the operator then produces a rapid vibration of the parietes of the chest and abdomen immediately over the liver. The effect is to relieve congestion of that organ and excite a healthy flow of bile.

Finally, the patient lies upon the back, and a thorough kneading of the abdomen is given, followed by pressure and vibration over the solar plexus. The circulation of all the abdominal viscera is thus stimulated, the passage of both chyle and fæces through the alimentary canal is aided, healthy secretion is promoted, undue accumulations of mucus are dislodged, and the great nervous centre of the organic system is roused into the highest state of activity. There are very few cases of constipation, however obstinate, which will resist a fortnight of this treatment daily, and many cases will yield in a week. The time occupied in carrying out this prescription is about an hour.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

SERVICE OF DR. JAMES H. HUTCHINSON.

REPORTED BY GEO. F. SOUWERS, M.D.

Mitral Disease, with and without Anæmia.

Gentlemen:—I propose this morning to offer you some remarks on some of the diseases of the heart, their complications and treatment, and such collateral matters as the subject naturally suggests. The patient before you is H. W., twenty-eight years of age, single and a domestic, born in Pennsylvania. She was admitted to the Institution January 12, 1881. Her father died of consumption, but her mother, brothers and sisters are alive and healthy. When a child she had an attack of acute articular rheumatism, but always enjoyed good health afterward until three years ago, when she had another attack, which confined her to her bed for several weeks. A few months after this last attack she began to have palpitation of the heart, pains in the chest, dyspnœa upon slight exertion, and at times more or less œdema of the lower extremities. Last July she was admitted into this hospital, at which time marked œdema and ascites were present, together with a pleuritic effusion on the right side. At that time the heart's action was labored and irregular, and a systolic and presystolic murmur were heard over the apex; there was present, also, a great deal of pain in the chest, especially in the region of the heart.

Five weeks after admission, and when the dyspnœa had almost disappeared, she weighed forty-

seven pounds less than upon her admission to the wards. She left the hospital during the latter part of October.

Since leaving here she worked steadily at her occupation as a domestic, until three weeks ago, when, having been exposed to cold and wet, she caught cold, and very soon suffered so much from dyspnœa that she was obliged to go to bed. She denies ever having had any specific disease. Upon her admission this last time the dyspnœa was marked, the pulse small and frequent, but regular, appetite fair, bowels and menstruation regular and no fever present. Although she has a dry cough, the examination of the lungs gives only negative results. The heart is somewhat hypertrophied, the apex beat being most distinctly felt in the sixth interspace, 1½ inches to the outer side of the left nipple; over the apex and systolic in time, a long, loud murmur is heard. Eyes prominent. Urine acid, specific gravity 1.012, and contains a small amount of albumen.

We have here a history of heart trouble due to a rheumatic attack, and the question arises as to whether the affection is of recent origin or whether the lesion dates back to the rheumatic attack of girlhood. It is a well-known fact that the cardiac complications in rheumatic attacks may be entirely overlooked if we depend upon the patient calling our attention to them. In fact, a complication may occur without, either at the time or in after life, giving rise to any symptoms that at all incommode the patient. I venture to say, therefore, that this lesion under which she is now suffering is due to the early rheumatic attack rather than the last, from the fact that heart complications are more apt to take place in the rheumatism of the young than in that of the adult; that is, the liability decreases in a direct ratio as the age increases.

The notes tell us that upon her first admission she was suffering with pleurisy, having taken cold, and that she was also the victim of ascites, and a general œdema of the limbs. This pleurisy rapidly subsided under treatment, and the dyspnœa almost altogether disappeared before her discharge, as well as the effused fluids (amounting, if we may judge by her loss in weight, to forty-seven pounds). Now I think that this disappearance of these symptoms goes to demonstrate that in the absence of acute disease a person will get along very comfortably and with no knowledge of the presence of a pathological condition of the central organ of circulation. On account of the prominence of the eyeballs you might be led to suppose that perhaps our patient was suffering under Grave's disease; but the cardiac signs are not those of this disease, and there is no enlargement of the thyroid gland, which almost always accompanies it. The further fact that in the colored race prominence of the eyeball is not unfrequent must also be remembered. Upon examining the heart, the impulse is perceived outside of the nipple and lower down than its normal position, the apex being in the sixth interspace and 1½ inches to the outer side of the nipple; further, there is an impulse in the second and third interspaces, which is more marked than the normal impulse, and precedes it by a distinct interval. There can be no question as to what causes are at work to produce this abnormal impulse; undoubtedly in addition to any further lesion which the organ may be the seat of, there is here present an hypertrophied condition of the left auricle; this has a large bearing on the question of prognosis, and should be carefully watched for, in examining cases of mitral disease.

Some of you may, perhaps, be disposed to regard the displacement of the apex beat to the left as a consequence of the effusion into the right pleural cavity; but the effusion is too inconsiderable in amount to have any such result. In addition to which, it is fully explained by the hypertrophy of the heart, of which there is abundant evidence in the increase of dullness in the præcordial region, which can be very distinctly made out, notwithstanding the presence of a very large and pendulous mammary gland. Examination of the arteries of the neck shows their beat to be rather feeble, whereas, if we had aortic regurgitation to deal with, their beat would, as a general rule, readily be distinguished, both by the finger and the eye; further, the artery at the wrist presents the characteristic pulse of mitral disease, being small and feeble in its beat and slightly irregular in character, like the heart's action. Upon auscultation a long, loud murmur is heard, which, beginning before, is prolonged through the systole, and is thus presystolic as well as systolic. This presystolic murmur is, probably, best observed by noticing that it begins before the carotid pulse is felt, and is, therefore, synchronous with the passage of the blood from the auricles to the ventricles. It is caused by constriction of the mitral orifice, interfering with this flow of blood, and is usually more distinctly heard at the apex.

The systolic murmur, of course, indicates the presence of mitral insufficiency. Now, mitral constriction is not a rare affection; the same condition of the valve which gives rise to mitral insufficiency will, and frequently does, give rise to mitral constriction, as, for instance, in those cases in which the auriculo ventricular opening has, in consequence of inflammatory action, become funnel-shaped. Now, if the auricle was weak and feeble, the blood would not be forced through the opening rapidly and forcibly enough to give rise to a marked murmur; in fact, the murmur might easily escape notice; in this case the impulse discovered in the third interspace indicates hypertrophy of the auricle, which thus sends the blood through with force enough to produce a murmur that is not only loud in front, but which can be as distinctly heard posteriorly, near the scapula. This murmur is also heard at the base of the organ, but is not so intense at the apex. It has, however, the same characters there, and is, unquestionably, of mitral origin. If we had to deal with aortic regurgitation we should have the second sound modified, which is not the case, for it is heard clearly and distinctly over the body of the sternum, and the aortic cartilage. The character of the pulse is not that generally seen in aortic regurgitation.

The formation of a correct diagnosis requires that attention be paid to these minute points. If a systolic murmur is heard, having its point of greatest intensity over the apex, especially if it is also heard at the inferior angle of the left scapula, it may generally be referred, without

hesitation, to mitral regurgitation. If, further, you find also a presystolic murmur, there can be no question but that more or less constriction is also present, and if there is also present a distinct and marked impulse in the third and fourth interspaces of the left side, you may safely diagnose a greater or less degree of hypertrophy of the left auricle.

This woman is, as the notes have pointed out, also the subject of a pleurisy, which, owing to its resultant effusion, has produced the distressing dyspnœa of which the patient has complained, and for which she has sought relief. This effusion is indicated by the dullness on percussion, and the absence of vocal fremitus over the base of the right lung. As indicative of the œdematous condition of the lungs, there are present sub-crepitant râles, which, however, under treatment, are disappearing; the œdema of the feet has also almost entirely gone. Examination of the liver shows it to be considerably enlarged, extending four fingers' breadth below the arch of the ribs. Already some diminution in its size has taken place, as it is not now as large as when she was first admitted; the left lobe is more enlarged than the right.

I have examined this patient's liver very frequently, to detect the pulsation which is said to be present in the organ when mitral disease exists, but have not been able to detect this symptom in this case. What this enlargement of the liver is due to I am not as yet prepared definitely to say. The patient is most certainly too young to render it at all probable, especially in the absence of pain and tenderness in the hepatic region, that it is due to cancerous degeneration. It is hardly likely to be caused by amyloid degeneration, for the albuminuria is too slightly marked to indicate a similar disease of the kidneys. Further, she has never had syphilis, or a prolonged suppuration; in other words, none of the conditions have been present which usually precede this form of degeneration. Thus, the heart's condition is the only thing to which I can trace the origin of the trouble. In mitral regurgitation there usually is present a greater or less degree of congestion of the liver, with a resultant jaundice. There are present, therefore, the conditions under which hypertrophic cirrhosis or fatty degeneration of the organ may take place.

I am rather inclined to regard this liver as being in what may be styled a fibro-fatty condition, which, however, is not wholly beyond the reach of treatment. The question now arises as to what shall be done to relieve the patient. She is the victim of many different diseases, and such a course must be pursued, that in relieving some, none may be aggravated. When she first came under treatment the heart was feeble and the pulse frequent, in consequence of which she had administered to her fifteen drops of the tincture of digitalis four times a day; of course, such a dose would hardly be permissible were the patient not under close observation; under ordinary circumstances the infusion is the better form of the drug, administered in from a teaspoonful to a dessertspoonful dose, three times a day; this drug may be styled a cardiac tonic and a diuretic, and though, of course, her improvement is due in some measure to the improved hygienic condition which she now enjoys, still, I think that no small part of it is due to the digitalis.

Referring to the notes of the case, I find that under this treatment the dyspnœa has rapidly decreased, and the pulse increased in volume. The pulse now beats eighty to the minute, and has gained in force. The digitalis having done its work should now be suspended, or administered in decreasing doses, and a stimulating diuretic and tonic administered: thus, as a diuretic, Basham's mixture would be advisable, and, as a tonic, six grains of quinine in the twenty-four hours. Although, of course, on account of the heart lesion and her inability to give up heavy work, a cure, or even an approximate cure, is impossible, yet she may thus be greatly relieved and life made bearable to her.

As a companion case to the one which I have just shown you, I would direct your attention to M. W., aged thirty, born in Pennsylvania, married, and a housekeeper, admitted to the hospital January 13, 1881. Her mother is living and healthy, her father died of cholera, her brothers and sisters of phthisis. She has had three miscarriages, the last four months ago, due, she avers to hard work and lifting. Seven years ago she had an attack of intermittent fever, but otherwise she has enjoyed good health, till recently. Three months ago she noticed that upon very slight exertion she would become short of breath, but otherwise she experienced no trouble or inconvenience. Six weeks ago, after having been working all day in a cold, damp room, she was taken with a sudden and severe pain in the left side of her chest, and this was followed by fever and shortness of breath, owing to which trouble she has been confined to her bed almost ever since. The pain in the chest continued for two or three weeks. Recently the fever has diminished, while the dyspnœa has attained such proportions that she is obliged to maintain a sitting position in order to obtain her breath; she has with this dyspnœa a short, dry cough. She has never had rheumatism, and denies any specific troubles. Upon admission she was very weak and anæmic, the tongue pale and moist, but clean; appetite fair; bowels constipated; pulse 72; temperature 99; respirations 35. She complained of a sensation of constriction of the chest. About two weeks since her legs were markedly œdematous, but this symptom has now entirely disappeared. You may notice that on her left leg is the scar of an old ulcer, which she had four years ago. Over the base of the left lung there is slight dullness on percussion; vocal fremitus is diminished somewhat, but respiration, although distant, is heard all over. Over the apex of the heart a systolic murmur can be heard, and the præcordial dullness is increased. Urine gives negative results. Undoubtedly we have here another case of heart disease, but one which does not seem to have had its origin in rheumatism, as we can obtain from her no history of her ever having suffered from this disease.

Careful examination shows that the apex beat is raised, being most distinctly felt in the fourth interspace, on a line with the nipple. It also shows us that there is dullness to the left of the

sternum, in the second interspace, in which no traces of vocal fremitus can be discovered. We have, in this elevation of the apex-beat and dullness in the second interspace, the evidences of a slight pericardial effusion. The endocardial murmur is most intense over the point where the apex is felt, and is very indistinctly heard over the usual position of the impulse. The careless observer might easily overlook it. It is also heard at the left base, and has here a slightly different character; so that, taking into consideration the extremely anæmic condition of the patient, and the fact that it is most intense in the recumbent position, I am disposed to regard it as due, in part, at least, to the condition of the blood. Indeed, I am doubtful whether the murmur heard over the apex is not also due to this cause. I am aware that Walsh has said that a hæmic murmur is never heard as low down as the apex; but while venturing to differ from this eminent observer, only with great hesitation, I must say that I have heard murmurs at the apex in anæmic persons which have disappeared upon their regaining their health.

The indications presented by this case—anæmia and effusion into two of the serous cavities—will be best met by prescribing Basham's mixture, in free doses, and by giving at the same time, if the patient's stomach will bear it, cod-liver oil and good diet.

Medical Societies.

A STATED MEETING OF THE PHILADELPHIA LARYNGOLOGICAL SOCIETY.

Held at the house of Dr. Geo. J. McCracken, 532 North 12th street, January 28th, 1881.

Before the meeting organized, Dr. Cohen exhibited a case of paralysis of the posterior crico-arytenoid muscles, the right vocal band being in the cadaveric position, associated with paralysis of the right pharyngo-palatine muscle, paralysis of the external recti muscles, paresis of the inferior oblique muscles of the eyeball, with paralysis of the extensor muscles of the lower limbs, and absence of the tendon-reflex movement; the whole representing the condition of locomotor-ataxia. In addition, there was marked hematuria. The nutrition was good. The origin of the disease was syphilitic, and the lesions were attributed to gummatous or other changes in the vicinity of the passage from the third to the fourth ventricle of the brain, and in certain portions of the cord.

The patient was doing fairly well under an active course of iodide of potassium, and was believed to be in as good a condition as was practicable.

Dr. McCracken exhibited the satisfactory progress of a case of laryngeal phthisis, with threatened stenosis, to which attention had been directed at the previous meeting. Dr. Cohen called attention to the manner in which one lateral half of the epiglottis overlapped the other, looking like a picture of a case recently published by Dr. French, of Brooklyn, and reported as a case of double epiglottis. In the present instance it was probable that the ulcerative process had so thinned the central portion of the epiglottis that the contraction of the ary-epiglottic muscles produced the deformity.

Dr. Jurist exhibited a case of tuberculosis of the larynx, from Dr. Cohen's hospital-clinic, in which cicatrization was rapidly advancing, under assiduous local treatment, *pari passu* with a marked increase in the weight of the patient, together with general improvement of pulmonary symptoms.

Dr. Jurist's report of the case is appended:—

Mr. J. L., aged 28, tailor, was sent to Jefferson Medical College Hospital, by Dr. Cohen, and presented himself December 22d, 1880. He gave the following history:—

In June, 1880, he was seized with pulmonary hemorrhage, soon followed by hoarseness, which has continued up to date, although much improved of late. The hemorrhages have not repeated themselves. Since then he has had frequent chest pains and some cough, accompanied by yellowish expectoration. In November last he felt, for the first time, some pain in the throat, which now does not amount to more than a sensation of dryness. His general health is good, and there is no evidence of hereditation. On examination there was discovered an ulcer in the inter-arytenoid fold, and evidences of consolidation at the apex of one lung. At Dr. Cohen's suggestion, he was put upon inhalations of carbolic acid and tr. benzoin. comp. (gr. v-℥j), and applications of equal parts of Lugol's solution and glycerine three times a week. About January 8th the inhalation was changed to one of simple hot water, and glycerite of tannin and sulphate of zinc, gr. xxx-℥j, used as alternate laryngeal applications. The change was not an improvement, and recourse was soon had to the old treatment, with the exception of the inhalation, which was not renewed. On the 31st of December he complained much of a feeling of stiffness in the chest and pleuritic stitches, for which he was given carbonate of ammonium, in three grain doses every four hours, and dilute tinct. iodine for external counter-irritation. On the 22d of January he complained of night sweats, to counteract which $\frac{1}{60}$ gr. of atropia sulph, at night, was ordered. To the above résumé of treatment must be added the usual prescription of cod-liver oil, in half ounce doses, three times a day.

Since his appearance at the hospital he has improved in every particular. His digestion is good, he sleeps well, and his weight is greater than when he considered himself in good health. He has gained seven pounds in six weeks. There is no evidence that the constitutional disease is progressing unfavorably.

The patients having been dismissed, the meeting was called to order by the President, who, in the absence of the Secretary, appointed Dr. Potsdamer as Secretary *pro tem.*

Members present, Drs. Allen, Cohen, Turnbull, McCracken, Sajous and Potsdamer. Guest, Dr. Jurist.

The minutes of the last meeting were read and approved.

Dr. Chas. S. Turnbull then read an interesting paper on Nasal, Post-nasal, Supra-post-nasal

and Pharyngeal Inflammations, considered with reference to diseases of the middle ear, with remarks, etc. (See page 197.)

This paper was then discussed by Drs. Allen, Sajous, Cohen and Turnbull.

It was then decided to meet next at the house of Dr. Jos. B. Potsdamer, 1428 Poplar street, and Dr. McCracken was appointed essayist of evening.

After reading the rough minutes, the meeting adjourned.

Jos. B. POTSDAMER, M.D., *Secretary, pro tem.*

NEW YORK STATE MEDICAL SOCIETY.

(*Continued from page* 181).

Thursday, February 3d.

The Society was called to order soon after 9 A. M.

The following papers were read by title: "A Biographical Sketch of Dr. Edward R. Hun, deceased," by Samuel B. Ward, M. D.; "A Biographical Sketch of Dr. Charles A. Robertson," by Dr. J. S. Mosher; "A Case of Cystic Degeneration of the Chorion," by Dr. James Chapender, of Medina.

Dr. R. Bell, of New York, presented a paper on "Reforms in regard to Coroner's offices," which gave rise to an extended debate. The paper outlined the many abuses which exist under the present system of making autopsies, and in the selection of coroners in New York city and elsewhere throughout the State.

Dr. Squibb, of New York, moved that the paper be referred to the publication committee, with a recommendation that it be published, and that it also be referred to the committee on legislation, with instructions to confer with the representatives of the Medico Legal Society as soon as possible.

The motion was seconded and adopted without further comment.

The president announced the following special committee on Ethical Revision, as ordered by the society, on the suggestion of the president in his inaugural address: Drs. Wm. G. Wey, C. R. Agnew, W. S. Aley, H. G. Piffard and S. O. Vanderpoel.

The secretary offered the following:—

Resolved, That the Medical Society of the State of New York advises the various county medical societies that form its constituency, to endeavor to secure the coöperation of the other incorporated county and district medical societies throughout the State, in the enforcement of the "Act to regulate the licensing of Physicians and Surgeons," passed May 29th, 1880. The resolution was adopted unanimously.

Dr. C. D. Stiles, of Oswego, read a paper on "A Device for Retaining Dislocations of the Clavicle at its Distal End."

Dr. Fox, of New York, followed with a paper on "The Benign Aspect of Syphilis," which was discussed by Drs. Bulkeley, Pooley, Ferguson, S. B. Ward, Piffard, Squibb and F. C. Curtis.

The committee on by-laws reported in favor of adding $100 additional to the compensation of the secretary, and $50 additional to that of the treasurer. Agreed to.

The committee on legislation recommended the adoption of the following:—

Resolved, That in the opinion of this Society it is desirable for the Legislature to thoroughly amend and revise the laws of this State in regard to the office and duties of coroners, and would recommend for their consideration the recent statute adopted by the State of Massachusetts.

Also, the following:—

Resolved, That the thanks of this society are due to the Medico-Legal Society of New York, and to Clark Bell, for the action they have taken in reference to the matter of coroners' law.

The resolutions were unanimously adopted.

Dr. Lewis Balch, of Albany, read a review of the second trial of Jesse Billings, Jr., for the murder of his wife, and explained the test made of the effect of shots into the human skull, exhibiting some half dozen skulls of the subjects operated upon, as well as that of the murdered woman. The fractures were described in detail. Owing to the limited time of the Society, he was not permitted to finish, but a resolution was adopted authorizing the paper to be published in the transactions.

The nominating committee then reported as follows:—

President—Dr. Abraham Jacobi, New York.

Vice President—Dr. William Govan, of Stony Point.

Secretary—Dr. William Manlius Smith, of Manlius.

Treasurer—Dr. Charles H. Porter, of Albany.

The usual Committees and Delegates were appointed, among the latter, those to the International Medical Congress, London.

The Society then adjourned.

During the session there was some discussion of the Registry law.

The secretary placed in the appendix to the transactions (1880), after the lately adopted by-laws, the portions rendered inoperative by the legislative enactments of last winter. The parts of sections relating to licensing to practice medicine are taken away from the Society by the "Registration law." This has practically been a dead letter for a long time, very few having been licensed in many years. Many members believed that diplomas or licenses are still too loosely granted, by reason of too many sources of obtaining them from the medical schools, and that there should, in some way, be a single standard for the State. Taking away the power to grant them from the sixty societies in the State was in the right direction, as all will agree, even though it was a power so little used.

—A third edition has appeared, this week, of Dr. Laurence Turnbull's work on "Tinnitus Aurium," enlarged, and including observations on imperfect hearing, the hygiene of the ear, aural vertigo, diseases of the naso-pharyngeal membrane, home instructions for the deaf, etc. The author has had unusual facilities to enrich his work by recent studies in Europe, and it will doubtless command a large sale.

Editorial Department.

Food and Fats as Expectorants.

Dr. T. Lauder Brunton says, in an article in the *Lancet*, January 1st:—

One of the most powerful expectorants is simply a little warm food in the stomach, and in cases of chronic bronchitis, in which the patients complain of violent coughing immediately after rising, one of the best expectorants is a glass of warm milk, either with or without a little rum, and a biscuit or a piece of bread about a quarter of an hour before they get up. A little warm beef tea will have a similar effect. After taking this for a short time they generally tell you that the sputum comes away much more easily than before, and they are not so much exhausted by it. But perhaps the remedy, *par excellence*, not only in cases of phthisis, but in chronic bronchitis, is cod-liver oil. Persons suffering from long-standing chronic bronchitis will often come to a hospital to beg for cod-liver oil, saying that it eases their cough far more than any cough mixture. Other oils or fats have not this power to the same extent as cod-liver oil. We cannot say positively what the reason of this may be, but I think there is no doubt about the fact. My own belief is that cod-liver oil is more easily assimilated than other oils, and not only so, but more easily transformed into tissues themselves. Whether it owes this property to its admixture with biliary substances or to its chemical composition, we cannot say. In his book, on "Fat and Blood, and how to make them," Dr. Wier Mitchell quotes a remark made by an old nurse, that "some fats are fast, and some fats are fleeting, but cod-liver oil fat is soon wasted." By this she meant that there were differences in the kinds of fat accumulated under the subcutaneous tissues of men, just as there are differences in subcutaneous fats which accumulate in horses. The horse fed on grass soon gets thin by hard work, while the fat laid on when the horse is feeding on hay and corn is much more permanent. Persons fattened on cod-liver oil soon lose the fatness again, and this, I think, points to the power of ready transformation which the oil possesses. Supposing that it does possess this power we can readily see how very advantageous it will be. In chronic bronchitis, and in catarrh and pneumonia, we have a rapid cell-growth, but want of development. The cells lining the respiratory cavities are produced in great numbers, but they do not grow as they ought to do. They remain, more or less, lymphoid cells, instead of developing into proper epithelium. They so rapidly form, and are thrown off so quickly, that they have not time to get proper nutriment, and if they are to grow properly we must supply them, not with an ordinary kind of nutriment, but with one which is much more rapidly absorbed, and is capable of much more rapid transformation in the cell itself than the usual one. This power is, I believe, possessed by cod-liver oil, and to its quality of nourishing the rapidly-formed cells in the lungs in cases of bronchitis and catarrhal pneumonia I believe its great curative power is owing.

Treatment of Ozæna.

The *Lancet*, January 1st, says: In several cases of chronic inflammation of the nasal and pharyngeal cavities, giving rise to offensive discharge, Dr. Poore has found decided benefit result from the use of a stimulant and antiseptic snuff having the following formula: biborate of soda, nitrate of bismuth, of each one drachm; disulphate of quinine, ten grains; iodoform, five grains. This snuff has the effect of stopping the fetor and greatly diminishing the amount of discharge from the nostrils. It is liable, as are all snuffs when used for similar conditions, to cake in the nostrils, and it is therefore necessary to thoroughly wash out the nostrils once a day. This may be done by means of a nasal douche, or the patient may easily be taught to snuff a lotion up the nose and allow it to run out of the mouth. A teaspoonful of glycerole of borax dissolved in a wineglass of tepid water forms an excellent wash for the nose, and with a little instruction patients learn how to wash out their nasal and pharyngeal cavities without the aid either of syringe or douche apparatus. In cases where the ozæna is of a simple kind, not due to caries or necrosis of bone, but rather to a sluggish, inflammatory action occurring in a scrofulous subject, considerable benefit is often derived from the administration of the sulphide of calcium in doses of half a grain (in pill), taken three times a day. It is often necessary to cleanse the nasal and pharyngeal cavities with a brush inserted through the anterior nares, and also behind the soft palate, so as to reach the summit of the pharynx. The brush may be moistened with glycerole of tannin, and after the cavities have been cleansed a little dry iodoform may be passed into the cavities on the tip of the brush.

The Operation for Club-foot.

In the Glasgow *Medical Journal*, January, 1881, Dr. Reuton strongly recommends Dr. Buchanan's operation. This is as follows:—

After division of the tendo-Achillis, the next stage is the division of those structures which maintain the incurvation of the astragalo-scaphoid joint, and which pull the ball of the great toe toward the heel. To effect this, the tenotomy knife is to be entered at the inner edge of the foot just behind the tuberosity of the scaphoid bone. It is to be kept flat and pushed under the skin till it reaches to the middle of the sole; then it is to be turned with its edge to the plantar fascia, which is to be divided with a sawing movement of the knife, the parts being kept in extreme tension by an assistant. When the knife has passed through this part of the fascia, the point is to be dipped down so as to divide as far as possible the septum of fascia between the

abductor pollicis and the flexor brevis digitorum, and then the whole of the muscular substance, down to the tuberosity of the scaphoid, is to be cut through; and before removing the knife from the aperture of entrance, the point may again be depressed, and the tendon of the tibialis posticus divided proximately to its insertion into the scaphoid.

Dr. Reuton adds, in eight cases of talipes and equino-varus, after dividing the tendo-Achillis, I have adopted the above treatment with most satisfactory results. In the first two cases a little difficulty was experienced in rectifying the deformity; this was evidently due to my not having effected a thoroughly free division of all the resisting structures, which Dr. Buchanan so plainly recommends. In the subsequent six cases the directions were more carefully carried out, with the best result, and in none was there any inconvenience experienced, either in the way of hemorrhage or irritation of any kind.

The form of splint used was, for the first two months, that recommended by Dr. Heron Watson, which consists of two pieces of tin, one being moulded to the calf of the leg and the other to the sole of the foot, and connected by a metal rod. The foot piece of this splint can thus be bent to any angle, and the limb is bandaged to it daily, after careful manipulation of the muscles; the angle is gradually increased until the foot is in good position. This splint is easily obtained for a few shillings, and can be applied by the mother or nurse of the child after one or two lessons.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a reprint from the *Medical Herald*, Dr. Wm. Porter, of St. Louis, discusses various points relating to phthisis. Though not believing that it is a self-limited disease, he does believe that it often responds favorably to treatment. He criticises, and we think justly, Prof. Flint's views on the self-limitation of phthisis. In treatment he offers nothing new, but we may quote this paragraph:—

The chain of cachexia, mal-assimilation and localization must be broken ere the victim can in any sense go free. A plain diet at regular intervals, such aids to nutrition as cod-liver oil, or better still, the well-known malt preparations, expecially the excellent combination of maltine with peptones, little if any tea or coffee, and where the tongue is much coated, a mild after dinner pill of myrrh and aloes, as commended by Fothergill; all this is plainly indicated in most cases.

——A case of Cæsarean section, with removal of the uterus and ovaries, by the methods of Porro and Müller, is described in a reprint by Dr. Elliott Richardson, of this city. It was successful and satisfactory. The writer says:—

A peculiarity of this operation is the large number of assistants required, owing to the fact that so many things have to be done at the same time and without the least delay. No one should undertake a Müller operation under the Lister antiseptic method without having eight assistants.

He describes the duties of each, and, in fact, they all do seem required.

—— The Fourteenth Report of the Columbia Hospital for Women, Washington, shows a prosperous condition and excellent results. Out of three hundred and sixty-four treated during the year only *one* died. Dr. P. J. Murphy, the surgeon in charge, is to be congratulated on such a result.

—— A biennial Report of the Albany Hospital fills a pamphlet of one hundred and twelve pages. The total number of cases treated in this period, was 3399.

——It is with pleasure that we speak in commendation of the *Illustrirte Vierteljahrsschrift für ärztliche Polytechnik*, a quarterly published at Bern, Switzerland, and devoted to the mechanical departments of medicine and surgery. It is abundantly illustrated, and gives all countries a fair representation. It costs only $1.00 a year—say $1.25 with postage, and as we can now send postal orders to Switzerland, any one here can easily forward this sum to the editor, Dr. G. Beck, and if a reader of German, he will be pleased with the result.

——One of Dr. A. Jacobi's admirable studies on Pædiatrics appears in a reprint from the *Archives of Medicine*. It is on anæmia in infancy and early childhood. He explains the pathology and treatment of the malady with great clearness. (G. P. Putnam's Sons, 182 Fifth ave., N. Y. City.)

——The Bulletins of the Public Health issued by the Supervising Surgeon General of the Marine Hospital Service, from July 1878, to June 1879, inclusive, have been reprinted in pamphlet form. This republication was very judicious, as any one can see by glancing at the index. That year, also, was a yellow fever year, and the history of the plague in Russia likewise coming into the period covered, render the volume a highly valuable one for medical history. The bulletins were published at the time, by the papyrographic process, and distributed in a limited number, but, of course, were not in such a shape as to be accessible to the general reader. Hence, the value of this reprint is that of an original work.

BOOK NOTICES.

Clinical Lectures on the Physiological Pathology and Treatment of Syphilis. By Fessenden N. Otis, M.D., Professor of Genito-urinary Diseases in the College of Physicians and Surgeons, N. Y., etc. N. Y., G. P. Putnam's Sons. Cloth, 8vo, pp. 116. Price $1 50.

This volume is a presentation from several points of view—the physiological, the pathological and the clinical—of the author's theory of syphilitic infection, and the proper treatment of the disease in reference to this theory. It is an enlargement of the opinions he has published in various journals from time to time during the last ten years. Dr. Otis rejects the fungus theory, and the corpuscular theory, and the chemical poison theory, and sets up another. This is a mysterious, metaphysical something which he calls the "syphilitic influence." He squarely denies the existence of a syphilitic "virus," and attributes all the pathological changes to this "influence," which leads to hasty cell proliferation.

Nothing whatever is gained by this hypothesis; it explains nothing, and sets up a word without meaning to act as a barrier to research. There is no organic "influence" outside of the chemico-vital laws of the organism; these explain all its transformations, and to them must finally be reduced all pathological momenta.

The practical portions of Dr. Otis' work can be read with profit. The last twenty pages are taken up with "class-room lessons on syphilis," which are clear and suggestive. His remarks on diagnosis indicate close observation of the ob scurer signs of disease.

A Treatise on the Principles and Practice of Medicine. By Austin Flint, M.D., etc. Fifth edi tion, revised and largely re-written. Philadelphia, Henry C. Lea's Son & Co., 1881. Half Russia, pp. 1150.

One would not risk much in speaking of this treatise as the most representative one yet written by an American author on practice. For many years its author has been an active teacher and fertile author in the profession, and his energy does not diminish with age. Seven years have elapsed since the last edition of his Practice was issued, and the present one is so far from being merely a revision of that one, that in his preface he announces it as "essentially a new work." He disclaims any fealty to views he previously expressed, and wishes his work to be judged, not by his own antecedent writings, but solely by the most recent results of scientific investigation.

This language has the right ring in it, and we are g'ad that a writer of such authority distinctly disclaims the *ipse dixit* style.

It will not be expected that an analysis of the work will be presented. Suffice it to say that the promise of the author, in the preface, to present a treatise well up to the latest studies is honestly maintained. It is greatly changed from previous editions, and the changes are improvements. We should be at a loss to point out any better treatise on practice, conceding certain opinions of the author as to the natural history of disease and overlooking the vagueness of much of his therapeutics.

Medical Diagnosis, With Special Reference to Practical Medicine. By J. M. DaCosta, M.D., etc., etc. Fifth edition, revised. Philadelphia, J. B. Lippincott & Co, 1881. 8vo, pp. 924.

As a standard work on general diagnosis, none in the language takes precedence of this by the Professor of Practice at the Jefferson Medical College. As an author, he happily combines unusual literary skill with a profound and practical knowledge of the branch of which he treats. Hence, for years his work has done away with the necessity for any other on the same topic. Stimulated by this deserved popularity, he has given the present edition a careful revision. This is especially observable in the chapter on the nervous system and that on the blood. It is extremely difficult, in the present state of neurology, to classify neural diseases symptomatically, as is necessary to Dr. DaCosta's plan; the anatomical classification is preferred by most recent writers; yet for diagnostic purposes the former is probably more convenient. There are, it is true, serious objections to it, and finally, no doubt, it will have to be discarded.

All the chapters of the work which we have examined show the marks of thorough editing. A number of new illustrations are scattered through the pages, and the recently invented mechanical aids for securing accuracy in the measurements of sensations are described with sufficient fullness.

The mechanical execution of the volume is such as we naturally look for from the eminent publishing house which issues it.

It is interesting to note that the appreciation of this work is so high that a translation of it has appeared in Germany, a country where so much native activity in medical investigation prevails. There is, in fact, no other work in any tongue, so far as we can recollect, that is of such real value to the diagnostician as this one.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA

THE CULTIVATION OF CINCHONA TREES

The indispensability of a constant and large supply of Peruvian Bark and its alkaloids has led several foreign Governments, Holland, England and France, to establish government plantations for cinchona trees, and in every way favor their production, as also to place every facility in the hands of those firms preparing the alkaloids. The results have been generally satisfactory.

In Bengal, last year, the Government plantations harvested 400,000 pounds of bark. In Ceylon, the area now under cultivation is about 8000 acres, with a total of 5,000,000 or 6,000,000 trees. It is stated that the yield of bark is already so plentiful that the price of quinine has been reduced to eighty-seven cents per ounce, and to fifty cents per ounce for preparations of inferior quality. Among the beneficent results anticipated from this experiment is the substitution, at no distant day, of quinine in place of opium, for medicinal use, in the fever districts of China. The Chinese supply of the latter baleful drug is now mainly obtained from India.

A single tree of the succirubra variety will produce, when fourteen years old, five or six pounds of bark. In Bengal, nearly a million trees are now planted out annually, and the profits of the undertaking are sufficiently handsome to make it attractive for private capital.

The soil and climate of the Dutch colonies in Java are still better suited for the cinchona trees than those of Bengal, and the plantations established there are very flourishing. As high as seven per cent. of quinine has been extracted from the bark in these localities.

The species cultivated differ. The Dutch prefer the *Ledgeriana* and the *Calisaya*. MR. THWAITS, a recent visitor to Ceylon, says there is no genuine *Calisaya* grown there. Both on that island and in Bengal the *succirubra* variety has been selected, but now, Dr. KING, government supervisor of the Bengal plantations, recommends grafting Calisaya on Succirubra stocks.

We have, on a previous occasion, referred to the possibility of establishing cinchona plantations somewhere in the warmer portions of this country, so as to make us less dependent on foreign markets. Southern Florida, southern California and Arizona have been suggested as possibly offering favorable sites. There are, however, doubts whether the climate of any of them is sufficiently warm, moist and equable. In a recent conversation with MR. HENRY S. WELLCOME, who has given, probably, more study to the subject than any other of our countrymen, and who has visited and carefully observed the native Cinchona forests of South America, he expressed the opinion that we could not find within the present limits of our country any spot combining the climatic conditions desired. Nevertheless, as there are many species of cinchona, some much hardier than others, we are not without hopes that some may yet be domesticated within the boundaries of the regions we have named.

This opinion has also been lately expressed by an intelligent writer in the New York *Daily Times*. He writes:—

It is quite probable, since there exists an in-

digenous pseudo cinchona tree in Georgia, that a good variety might be made to grow there, and it is even possible that by grafting with slips of the best varieties, good bark might be grown. There is no possible reason why, in many portions of California, cinchona plantations might not be started; certainly, the experiment is worth trying. It should be mentioned, however, that from some unknown causes, the cinchona does not produce the much desired alkaloid in all situations. The tree may grow apparently with the utmost vigor, but when its bark is tested no useful products are forthcoming. Quite lately a sample of bark, having all the appearance of the best South American, grown in Mexico, was sent to a leading house in New York to examine. On analysis it was found not to contain any quinine. Before the cultivation of the cinchona tree should be attempted in the United States, the most thorough experiments should be made with all the best varieties taken from many sources. It would be no difficult task for our Government to obtain slips of the cinchona tree and distribute them. It does not seem, from the results already obtained in Ceylon, India, and Jamaica, that the cinchona tree is limited to one exact area. It would be even quite possible that the cinchona, like many other trees, improve by translation into other countries.

In this connection, we may note that, as we predicted at the time, the removal of the duty on quinine has not lowered the price of that article. Prior to the removal of the duty, owing to an epidemic in Russia and fevers in the South, quinine was very high, exceptionally so, and was worth $3.40 per ounce. From a speculative demand it advanced to even $3.50, after the duty was taken off.

Last year the average of cost was about $2.90, the maximum being $3.25, the minimum $2.50. This is about the same as the quotations for quinine between 1873 and 1876.

Meanwhile the production of quinine in the United States has fallen off about 40 per cent.—from an annual average of 900,000 ounces to an average of 500,000 ounces. In place of it, the manufacturers are pushing with vigor substitutes, such as cinchonidia, which is protected by a duty of 40 per cent., and various mixtures of the commoner alkaloids, which are vended at a larger profit than the sulphate of quinine would allow. Whether the numerous patients have benefited by this change, according to the confident predictions of the friends of "free quinine," can be imagined. We have frequently said that the removal of the duty was a piece of botchwork and a blunder, and the above facts do not alter that opinion.

Notes and Comments.

The Organisms of Typhoid Fever.

In the seventieth volume of Virchow's *Archiv*, Dr. Eberth describes his discovery of bacillæ in greater or less numbers in the swollen mesenteric glands and in the spleen, in twelve out of twenty-three cases of death from typhoid fever. These organisms are about equal in size to the putrefactive bacillæ found in blood; like these they are slightly rounded at the ends, but have a less strongly marked outline, and are less deeply stained by methyl violet. The more protracted the course of the disease the less numerous they seemed to be. Ordinary putrefactive bacillæ were seen also, in the lymphatics and in parts of the intestine, but were easily distinguishable from the enteric fever bacillæ, by the difference in color which they showed when treated with aniline dyes. The organisms under consideration were quite distinguishable also from those of diphtheria and pyæmia. Eberth regards it as probable that the bacillæ stand in some relation to the typhoid process, but what the nature of the connection really is has not yet been shown.

The Parasite of Malarial Fever.

Professor Tommasi-Crudeli, of Rome, writes to the *Practitioner* some further accounts of the fungus or spore, which he calls *bacillus malariæ*, and which he looks upon as the cause of malarial fever. Experiments made on animals have shown that the principal *nidus* of the parasite is in the spleen and in the marrow of the bones, the organs in which we constantly find the most serious pathological changes in those who die of this fever. He believes that the production of new generations of parasites in these seats varies in extent and in rapidity, according to the condition of the individual, and probably, also, according to the quality of the soil from which the parasite originally came; which explains the great variations which we meet with in the duration of the intermittences of this fever. His theory is that the febrile attack does not take place until the discharge of the parasites from their special *nidi* has gone on to such an extent as to accumulate in the blood a vast number of these organisms. The chills of the febrile attack are produced by the simultaneous irritation of all the vaso-motor nerves, due to the presence of this army of invaders in the circulatory system. These invaders

find in the blood the conditions most adapted to accelerate their development and their progress to maturity (*i. e.* a high temperature, abundant means of nourishment, and oxygen stored up in the red corpuscles), and hence their disintegration is completed in the *acme* of the fever; while, on the other hand, the changes in the component elements of the blood and tissues, due to their multiplied acts of assimilation and excretion, affords an explanation of the development of the febrile heat.

Size and Weight of Neonati.

An article by Dr. Francis Ogston, Jr., in the Edinburgh *Medical Journal*, for January, gives the average length and weight of two hundred native new-born Scotch children. The average length is nineteen to twenty inches, the average weight six to nine lbs. He observes, that on consulting our various medico-legal and obstetrical authorities, we find a wide diversity of opinions on this point, as the following figures, drawn from various sources, will show:—

Length, { Minimum, 16, 18, and 19 inches.
Maximum, 18, 19, and 20¼ inches.
Mean, 18, 19, and 20 inches.

Weight, { Minimum, 4, 5, and 6 lbs.
Maximum, 7, 8, and 11 lbs.
Mean, 6¼, 6¾, 7, 7⅛, 7¼, 7⅜, 8⅛, 8½, and 9 lbs.

A reason for this wide divergence of opinion may be found in the fact that most authors have made use of data drawn from the records of various countries and nationalities, which would give rise to serious error, since the children of different nations and climates appear to vary in size and weight in a similar ratio to the adults.

The Contagion of Enteric or Typhoid Fever.

In an address on hospitals, before the Social Science Congress, at Edinburgh, Sir John Rose Cormack, M.D., said that, in reference to the contagious nature of typhoid, observed facts justify the following conclusions:—

1. Enteric fever is a contagious disease, the contagium of which exists in the intestinal excreta.

2. That the contagium is generally diffused by water or milk.

3. That perhaps the winds may spread the contagium when the sun-dried intestinal excreta are diffused as dust in the atmosphere.

4. That, for the safety of the community, cases of enteric fever ought to be isolated at home, in hospitals, or where the excreta can be systematically destroyed or disinfected.

5. That the gathering together enteric fever patients in well-organized hospitals is neither dangerous to their inmates nor to the inhabitants of the vicinity.

Hot Ice and Cold Fire.

Among the miracles of modern science are ice so hot that it burns the hand, and fire so cool that it is agreeable to the skin. The former has been obtained by Prof. Thos. Carnelly. *The Chemical News*, states that he has produced solid ice at temperatures so high that it was impossible to touch it without burning one's self. On one occasion a small quantity of water was frozen in a glass vessel which was so hot that it could not be touched by the hand without burning it. Ice was kept for considerable lengths of time at temperatures far above the ordinary boiling point, and even then it sublimed away without any previous melting. These results were obtained by *maintaining* the superincumbent pressure below 4.6 mm. of mercury, *i. e.*, the tension of aqueous vapor at the freezing-point of water.

On the other hand, the *Progrès Médical*, January 22, describes how M. Kordig has been exhibiting in Paris a new burning fluid, which he pours into his hand, ignites, and allows to burn with a clear, bright flame, until it is all consumed; or he dips his hat into it, sets fire to it, and with the flame blazing to the ceiling, walks around with it on his head! The explanation is simple enough. This fluid is a petroleum product, which boils at 90° Fah. and its vapor, which is the part that flames, does not heat the liquid itself beyond that temperatnre.

Pitting of Smallpox.

Dr. Schwimmer, in the *Gazette des Hôpitaux*, advises a mask, to be formed of very pliable linen cloth, leaving apertures for the eyes, nose and mouth. The inside of this is to be smeared with one of the following liniments: (1.) Carbolic acid, 4 to 10, olive oil, 40, and prepared chalk, 60 parts. (2.) Carbolic acid, 5, olive oil and pure starch, of each 40 parts. (3.) Thymol, 2, linseed oil, 40, and chalk in powder, 60 parts. The mask should be renewed every twelve hours. Compresses impregnated with one of these mixtures may also be placed on the hands, and on any parts of the face with which the mask does not come into exact contact.

Unruptured Hymen in a Prostitute.

In medico-legal cases it is not unfrequently assumed that the persistence of the hymen is evidence that intromission has not been effected.

The error of this assumption was pointed out lately, before the Medico-Chirurgical Society of Edinburgh, by Dr. A. G. Miller, who showed a drawing of an unruptured hymen, which he had discovered in a prostitute admitted under his care in the Lock Hospital, for gonorrhœa and syphilis. The hymen was lax and freely movable, which probably accounted for its escaping from injury. We believe such cases are not very rare.

The Relations of Locomotor-ataxia.

The coincidence of locomotor-ataxy with insufficiency of the aortic valve, has led Dr. J. Grasset (*Montpellier Médicale*, 1880) to the opinion that their relation is a causal one. Possibly the severe pains of the spinal degeneration may give rise to such cardiac disturbances as to affect the innervation, and hence the nutrition, of the valves.

Dr. O. Berger (*Centralblatt für Med. Wiss.* No. 42, 1880) has observed that in chronic cases of tabes the sense of touch and the cutaneous sensibility, after being long impaired, returns and continues to a full normal degree. What is more strange, he notes one case where patellar tendon-reflex, after having been absent for years, also returned with unimpaired force.

Treatment of Frostbite.

It is stated in the *Allg. Med. Cent. Zeitung*, that the "house mixture" for frostbite, in the Rudolf's Hospital, at Vienna, is:—

℞. Acidi nitrici diluti.
Aquæ cinnamomi, āā partes equales.

This is applied on frozen hands and feet, but only when they are red and painful, with *unbroken skin.* When the nose, cheeks or ears are frozen, the above must be diluted with ten times the amount of distilled water. It should be applied once a day, small quantities being mopped on the skin and then lightly wiped. When ulcers or broken skin is present, they must first be brought to partial cicatrization before this means is applied.

Parenchymatous Injection of Arsenic for Enlarged Spleen.

In Prof. Mosler's clinic, in Greifswald, some experiments were made last summer, of the injection of Fowler's solution into the substance of the spleen, in order to reduce enlargements following on malarial fever. The patients were prepared by daily enemata of amorphous muriate of quinine, and after the injection they were kept at rest with an ice bag to the part. The injection was made with a large-sized Pravaz syringe, the point being pushed well into the parenchyma of the spleen. The solution should at first be diluted with four or five times as much water. The cases recorded in the *Deutsche Med. Wochenschrift*, No. 47, 1880, seem to have all improved under this treatment.

Correspondence.

Apparitions or False Conceptions.

Ed. Med. and Surg. Reporter:—

Much has been said and written on the subject of false conceptions, both visual and auditory, and of the causes of this mental derangement. The hideous phantasms, distorted appearances and fearful hallucinations which are usually attendant upon such attacks are very afflicting. However, it should be understood that these false conceptions are not *always* attended by unpleasant feelings; often the representation is of such a character as to cause a sense of real pleasure or consolation. A number of instances might be cited where persons were rather entertained than displeased by these illusions.

To be subject to these hallucinations need not be a mark of any intellectual deficiency.

It is evident that the more vivid is a person's imagination, the more subject is he to these delusions of both vision and hearing.

The case I will here report is of young Geo. W., student at a High school on the Pacific coast. He had attended two full courses of study, almost without intermission; and seemed, so far as outward appearances were concerned, to be in a sound state of both mind and body. Naturally ambitious, working most incessantly, day and night, had evidently unbalanced his mental capacity. He describes the occurrences as follows:—

"I was boarding with a classmate near the town of H——; we were nearly of the same age and were constant companions. In February, 1877, I, with the rest of a class of five, was to be subjected to a critical examination in the higher branches, including Geometry and Astronomy. At this time I was in my nineteenth year and was ambitious of my skill as a mathematician and logician. Walking up to the Examination Hall in company with my room-mate, I saw, or seemed to see, two fellow-students coming toward the building, at a distance of about thirty yards. Thinking no more of it, I entered the building and awaited the arrival of the other members of the class. My friend stepped out, and I, expecting the two first seen, went to the door but did not see them; thinking that perhaps they were in the vestibule, I returned to the recitation room and took my seat. I had hardly done so, however, when I heard my name distinctly called, as I supposed, by one of the class. Again going to the door, I peered in every direction, in vain, for the speaker, went in all the rooms and on the grounds. This apparent calling was repeated a number of times, with more or less distinctness. Half doubting my senses I awaited the arrival of

the class. In the course of half an hour the two persons whom I had imagined I saw presented themselves in reality, and until then I was not convinced but that I had at first seen them in reality. After returning to my room in the afternoon, I was alone for some hours. Time after time I could hear my name uttered, but on approaching the spot whence the sound seemed to proceed no one could be discovered.

"I at once understood that these hallucinations were not real, but were the result of a diseased mind, or some undefined cause. In this case my terror was overbalanced by my judgment. So far, these delusions did not seriously trouble or affect me; however, I was from time to time annoyed by the sounds, not only of my own name, but imaginary of those in distress. Yet I was not frightened, except, as my natural judgment suggested my mental condition."

Shortly after the occurrences above related Mr. S. concluded his course at school, but continued his application to study, under the tuition of a former teacher, which did not in the least tend to subjugate this malady.

"At another time," says he, "I was residing at my home in the country, when, after the evening meal, I took a little stroll of a few minutes before again resuming my studies. I was walking along the path leading to the house, when, suddenly, I beheld the appearance of two acquaintances, a lady and gentleman, one of whom had previously been my student, and later both had been my college mates. Everything looked natural, and consequently, I did not at first understand but that I did indeed see them in reality. For an instant turning my eyes the other way, I could no longer behold them. I then knew the truth of the matter, and, as a natural result, felt somewhat badly. I had proceeded but a few feet further, when I beheld another spectre, so terrible to me that I have not language to express or pen power to describe it. The appearance was as nearly that of my own as is possible, except that the figure appeared worn and emaciated, as from some secret trouble or mental derangement. This vision was never afterward presented to me, till, after recovering from a severe sickness, I went to the looking-glass, and saw the precise representation that had previously appeared to me in the form of an apparition. After this I was but little troubled by anything of the kind, though I was frequently, more or less, attacked by these hallucinations, till about two years subsequently, when the ailment assumed a new aspect. The attacks were more like those of apoplexy. During these periods, which usually last but a few moments, the agony expressed must be terrible, from appearences, to those around me. Aside from this I am in perfect health." T. S. P.

Fresno, Cal.

[Such hallucinations are quite common, and still more remarkable when seen by several persons at the same time. When recurrent, they are generally epileptoid in character. Swedenborg is a well known example of recurrent hallucinations. We have in preparation a "Special Report" on mental diseases, which will give other instances.—Ed. Reporter.]

Was it Relaxation or Spasm?

Ed. Med. and Surg. Reporter:—

I read, recently, an article on "Anæsthesia in Labor," by Dr. D. M. Culow, of Whitesville, Ind., in the *Obstetrical Gazette*, in which he reports a case, the main points of which are as follows:—

Mrs. B., sixth confinement, breech presentation, os rigid, appealed for chloroform, which was administered during each pain, but not sufficient to produce stupor. The breech and trunk were born in the course of a few hours, and just the moment the neck reached the external genitalia the pains ceased completely, and with all the known methods to establish them again, not a pain came till about twenty minutes had elapsed. The consequence was, complete asphyxia of the child, with no chance of resuscitation."

The Doctor attributes this to the effect of the chloroform, and "advises young physicians to use anæsthetics only in extreme cases, and let natural labors rest with nature's aid."

He does not inform us as to the condition of the uterus, whether it was in a condition of relaxation or *spasm*. If in a state of relaxation, he should have reached up into the uterus, hooked his fingers into the mouth, brought down the chin and delivered the head, thereby saving the life of the child; the uterus would have then have contracted of itself, or by grasping the fundus with one hand through the abdominal walls, and inserting the other into its cavity, immediate contraction would have taken place.

If the uterus was in a state of spasm, he should have crowded the chloroform; if that did not succeed, given opium, and waited for the spasm to subside.

My opinion is, that the uterus was in a state of tonic spasm, and that the chloroform had nothing to do with the condition.

Now for a case in point:—

About 9 P.M., January 25th, 1881, I was called to attend Mrs. C., in her third confinement. On my arrival I found her in the care of an ignorant midwife, who informed me that the lady was taken sick about noon, and that everything had progressed well till the feet presented at the vulva. Being unable to complete the labor, she sent for me. I found the child dead, with the lower extremities and part of the body protruding from the vagina; the os firmly contracted around the thorax. After exercising a good degree of patience and some force, I was enabled to insert my finger through the os, and finally succeeded in bringing down the arms.

The uterus being in a state of rigid spasm, the os contracted so firmly around the neck of the child that it seemed as if held in a vise, and I was utterly unable, even under the effect of chloroform, to insert my finger into its cavity. I now sent back to town, a distance of four miles, for my friend, Dr. E. R. Willard, to assist me, and in the meantime gave her gr. x of pulv. ipecac et opii, and sat down to wait for his arrival. In about half an hour she began to complain of pain, and upon examination, I found slight relaxation of the os. After awhile I succeeded in passing my index finger into the cavity of the

uterus, and hooking it into the mouth, brought down the chin. By pulling steadily with my finger, at the same time pressing upon the uterus above, the head became engaged, and I succeeded in terminating the labor before the doctor's arrival. I neglected to state that she had not had any pain from the time her husband started for me until after she began to come under the effects of the opiate.

Here was a case in which chloroform produced no relaxation, but which yielded readily to an anodyne. I have used chloroform for years in my obstetric practice, and in a great many cases have often seen total cessation of uterine contractions from its effects, and been obliged to stop its administration, yet have never seen any untoward effects. It seems to me that the Dr.'s case has no bearing on the subject of anæsthetics in labor, and if his advice was followed, woman would be denied one of the greatest boons of the age.

I do not pretend to say that there is *no* danger in the use of anæsthetics, but I think that there is very *little* if ordinary care is exercised in their use.

D. J. MERRIMAN, M.D.

Wilmington, Ill.

A Complicated Case of Prolapsus Uteri.

ED. MED. AND SURG. REPORTER:—

Since it has lately become the fashion to record, through the pages of the REPORTER, errors in the investigation and treatment of cases, I venture, with less reluctance, to expose the details of a case which has given me a great deal of trouble and annoyance. I can, however, not forbear to give myself the advantage of the natural and usual shield of declaring that I make no pretensions to being a specialist, hoping thereby to mitigate the censures and criticism of your readers. But whatever may be the consequences, here are the facts:—

About a year ago, Mrs. B., aged twenty-four, was delivered, after a prolonged and painful labor, of her second child. The presentation was by the breech, though I learned that the first child had come down by the vertex. Her lying-in was attended by nothing unusual, except considerable prostration, and a slow recovery of strength.

Some weeks after her delivery I was sent for, when she complained of much discomfort and heaviness in the lower abdominal region; the bowels were constipated, and her rest at night was poor, formication being one of her most disturbing symptoms. She had just passed through a profuse menstrual flow of a week's duration, which had not yet entirely ceased, and this notwithstanding the fact that she was suckling her child. I prescribed potass. bromid. in twenty gr. doses, three times a day, and ordered a Lady Webster's dinner pill to be taken at bedtime, when the bowels had not moved during the day.

She told me she had suffered from a similar train of symptoms within a month of her first confinement (which occurred twelve months before her second), and had only recovered from them upon the supervention of her second pregnancy.

I saw her a few times, at intervals of five or six days, and finding no improvement made a vaginal examination. The uterus was unduly large and slightly prolapsed. I applied a pessary, which fitted well, but was sent for next day, and obliged to remove it on account of the pain it caused. At the same time the rapid pulse, high temperature, hypogastric tenderness and other signs pointed to the development of pelvic inflammation. After confinement to bed for the greater part of two weeks, subjected first to antiphlogistic and later to tonic treatment, she again moved about the house, and soon began to take part in the domestic service of the family. She was again very much in the condition I have described as applying to her previous to the introduction of the pessary. I continued using constitutional remedies, which, up to this time, the present date, include ergot, cinchona, strychnia, chlorate of potassium, iodide of potassium, iron, and others, till by consecutive trial I have exhausted the whole line of tonics and alteratives. I have employed chloral, bromide potassium, henbane, lupulin, opium, etc., at night.

Some time after the attack of metritis, I examined her with the speculum, and finding the os tincæ ulcerated, made local applications, which soon obliterated the ulcers, but left the os swollen and turgid. I proceeded with weekly applications of glyc. sodii boratis, applied on a plug of absorbent cotton, and allowed to remain for twelve to sixteen hours. The appearance of the parts indicated progressive improvement, but still there was little improvement in her general condition.

During August she passed through an attack of dysentery, and in September she had intermittent fever. These attacks precluded the use of topical measures to the uterus, and in October, when they were resumed, the cervix was as much congested as ever. I then began to puncture the mucous membrane of the neck, so as to cause slight oozing from numerous points, extracting in this manner from a half to one ounce of blood at every sitting. I directed her to syringe the vagina with warm water, within half an hour after each operation, so as to favor the bleeding. The congestion was again subsiding, but still no material general improvement took place.

Several times during the summer I had urged her to consult Dr. Goodell, of Philadelphia, but she would not consent. I now advised her to leave the matter, for a time at least, to nature, abandoning all treatment.

In the first week of January she was taken with diphtheria. The case was at no time alarming, and she made a slow recovery. On January 19 I again applied a pessary, but it was not retained more than twenty-four hours before it slipped away, as she walked over the floor. She said it seemed to do her much good while it remained. On the 25th I applied a larger size, but she at once experienced such severe pain that I removed it before leaving the house, I then made a digital examination, and recognized, for the first time, a small tumor in the posterior cul de sac, exactly in the median line. It could be easily moved upward or laterally, and its size, consistence and sensitiveness, indicated plainly that it was an ovary. On being touched the pain

was acute, "darting into every part of the body," as she expressed it.

I am now convinced that this displacement has existed throughout the whole time of treatment, and that, though I have examined her, standing, on her back, on her right and on her left side, I never discovered it. It is very probable, that on account of its mobility it was frequently out of reach of the finger, or that the prolapse of the womb, which has lately considerably increased, has only recently dragged it down sufficiently far to be easily felt. True, I have all along given the ovaries credit for being the seat and source of much of her pain, and have for months had her paint the inguinal regions with tr. iodinii, and have applied belladonna plaster and blisters, but rather under the supposition that they were the seat of chronic engorgement than for any other reason.

The woman is in a position that requires her to do housework and attend her two children, and I cannot see what, under these circumstances, I can do for her, except to give her a well-fitting abdominal supporter, and an occasional course of tonics. Ovariotomy, of course, would suggest itself only as a *dernier ressort*. She now takes

℞. Ac. phosph. dil., f. ʒ vj
Liq. strychnia, f. ʒ ij. M.

Sig.—Thirty drops after each meal, well diluted.

Poisoning by Chloral.

[Dr. S. Taylor inquires of us the minimum fatal dose of chloral, and the symptoms of poison ing by this drug. We referred his letter to Dr. H. H. Kane, whose able studies on this and other narcotics are well known, and he kindly furnishes the following interesting reply. Ed. Reporter.]

Ed. Med. and Surg. Reporter:—

In reply to Dr. Taylor's letter, just at hand, I would say that the smallest amount of chloral to which death has been attributed is ten grains. It is reported by a writer in the London *Lancet*. Death from twenty grains, in two doses of ten grains each at an hour's interval, in a perfectly healthy German woman, is given by Ingalls, in the Chicago *Medical Journal and Examiner*. It was administered to dull the pain of having a tooth drawn. Dr. Chas. Hart, relates the case of a lady suffering from neuralgia, who died thirty minutes after a dose of twenty grains (New York *Medical Record*, 1871, p.164). "G" (*Lancet*, June, 1871), reports a death from fifteen grains in a patient who had manifested an idiosyncrasy regarding opium and chloroform. Fuller reports a death from thirty grains, given to relieve insomnia in a young lady (*Lancet*, June, 1871). For a large number of cases of death from doses of chloral varying from ten to six hundred grains, I would refer Dr. Taylor to my articles on "Deaths from Chloral," in the New York *Medical Record*, December 25th, 1880, and January 1st, 1881, also to an article on "Poisoning by Chloral," soon to appear in the same Journal.

The symptoms of chloral poisoning will vary according as death takes place by cardiac or respiratory failure. In the former, in brief, there is gradual or sudden failure of heart power, dilated pupils, blanched surface, fluttering pulse, almost imperceptible heart sounds, cold extremities and death. In the latter, dilated pupils (occasionally normal, still more rarely contracted), flushed and finally livid face, slow, stertorous breathing, congestion of the conjunctivæ, either rapid or very slow, full pulse, *profound coma*, involuntary evacuation of fæces, and finally death. Occasionally there is delirium.

Small doses given for a long time may end in sudden death. Given at night, in small doses, the patient may sleep soundly, and, on attempting to rise in the morning, fall dead. (See cases by F. Jolly, *Bayer. Ärztl. Intell. Blatt*, N. Y., *Medical Record*, 1871, p. 324.)

The time after taking at which the effects of chloral manifest themselves varies with the temperament of the patient, the disease for which given, the amount of drug used, and the method of administration. From fifteen seconds to three hours. In intravenous injection the effect is almost immediate; somewhat less rapid when administered subcutaneously; and acting in about the same time when given by the mouth or rectum. In the last two the usual time is from fifteen to forty minutes. Never give larger doses by the rectum than by the mouth.

In poisoning by strychnia, in tetanus, and, in fact, all convulsive disorders, large doses of chloral are necessary, if any good result is to be obtained.

For the contra-indications to the use of chloral, I would refer the Doctor to the articles already spoken of. They are, in brief, anæmia, great age, respiratory and cardiac disease, delirium tremens with weak pulse, disease of the arterial system, conditions of hyper-alkalinity of the blood, etc., etc., etc.

H. H. Kane, M.D.

191 *West 10th street, New York city.*

Stones in the Bladder.

Ed. Med. and Surg. Reporter:—

I forward to you the following history: Col. D., aged 54, occupation farmer and contractor, in the year 1870, while engaged in constructing a levee on the Mississippi river, from no known cause, there was retention of urine. After hot baths and all means at the patient's command failed, he was rowed to a town on the Kentucky side, and called a physician, who attempted to relieve him by the catheter, but failed; he called another physician, older than himself, with no better results. The patient then boarded the first steamer for New Orleans, was on the journey three or four days, all the while suffering tortures, being partially relieved by morphia and sitting in a tub of hot water. The urine would dribble from him; the only reason the bladder did not burst. On his arrival at New Orleans he called a physician, who succeeded in introducing a catheter, giving the patient immediate relief, but leaving the bladder paralyzed ever after, and for ten years he has had to relieve the bladder with the

catheter. From the first the prostate gland became enlarged, and remained so until his death.

He consulted me April 1, 1880, and gave the above history. I told him my opinion was stone, and I would sound him, but being busily engaged in business, he postponed it for a month or two, gradually growing worse all this time. Finally, in June, he consented to have the examination for stone. I introduced the sound into the bladder with the greatest ease, as the urethra was very large, from the frequent introduction by himself of the catheter, but found it impossible to turn the sound down, from the acute pain it gave him, there being great inflammation of the coats of the bladder; and another difficulty was the enormously enlarged prostate. So, for the time, gave over any further efforts to sound, until we could allay the inflammation and extreme sensitiveness of the bladder, giving treatment for that and washing the bladder with carbolic water and phenol sodique. After some time, with this treatment, I again, with the help of Drs. Pace and Graham, attempted to find the stone, but failed, from the same cause as at first trial. All this time I felt sure there must be stone. But authors say you must not operate unless you can feel the stone, and at the same time say a stone may be so imbedded in the coats of the bladder that it cannot be felt. What are we to do? The consulting physicians could not determine what was best, but advised to wait for further developments, which we did. About two weeks after the patient had a severe hemorrhage from the bladder, that so prostrated him his life was despaired of. We succeeded in checking the hemorrhage by the hypodermic use of ergotine and by throwing astringents into the bladder. After the patient rallied a little he insisted upon an operation, for it was but death either way. I deemed an operation at this time to be hazardous. The patient gradually grew worse, in spite of tonics, nourishing food, etc., and on the 10th of September died. Autopsy found four stones as large as a medium white-alley, of phosphatic variety. Query: If we had operated six months before, and there had not been stone, would not the operation have been justified for the cure of the enormously enlarged prostate? The patient's father died from some disease of the bladder; no post-mortem. Also, has a brother in the State of Tennessee suffering from same trouble.

This is one of the failures you bid for.

Dallas, Texas. G. Beaumont, M.D.

Disuse of the Axillary Pad in Fractured Clavicle.

Ed. Med. and Surg. Reporter:—

I see in the Half-Yearly Compendium, of July, 1880, page 232, that Dr. L. A. Dugas claims to have been among the first to treat fractures of the clavicle with a sling bandage and without axillary pad.

I would like to know if he did not attend the lectures of Dr. Benjamin Dudley, of Transylvania University, at Lexington, Ky.?

Dr. Dugas' reasoning and treatment is about the same as Prof. Dudley gave his classes in 1831. E. Foster, M.D.

Louisville, Miss.

News and Miscellany.

The Accuracy of Clinical Thermometers.

We accede with pleasure to a request to publish the following card to the Medical profession, from the Winchester Observatory of Yale College.

The competition of business, coupled with the entire absence up to this time of any large observatory in this country paying special attention to thermometry, to which authoritative appeal could be made, has so affected the manufacture of thermometers for medical purposes, that it seems necessary to issue a card briefly indicating the errors commonly found to exist, and to explain why, in this case, the representations of the dealers may be at fault, through the want of a proper understanding of the subtle errors to which medical thermometers are liable.

Too great a desire to economize time, good material, and skilled labor has led, in the making of thermometers, to the following faults: 1. The graduation is sometimes started from one point of the scale, near the normal, and the size of the capillary tube is guessed at. No upper point being fixed by the maker, the higher graduations may be erroneous to the extent of several degrees. 2. Too much air separating the index from the column of mercury causes the index to rise with a jerky motion; air above the index forces the index down when the thermometer is taken away from the body. In some thermometers errors from this cause amount to two degrees at high temperatures. 3. New thermometers increase their readings rapidly during the first months after manufacture, so that instruments which were right when made may change their indications as much as two degrees within a year.

It will be seen that these errors are not such as the dealer can readily detect. Even in those cases where a dealer is provided with a standard thermometer with which comparisons could be made, it is a difficult matter to determine the errors of the standard itself, and the unsupported representations of dealers and druggists, therefore, though made in perfectly good faith, cannot, from the nature of the case, afford the physician satisfactory evidence that any thermometer he may buy is not affected with errors, which in many instances under our observation have amounted to several degrees.

Following the example of the Royal Society's Observatory at Kew, at which during the past year upwards of five thousand thermometers were examined, this observatory has established a department to which any physician or other person may send thermometers, by mail or express, and upon the payment of a small fee receive certificates of their exact errors. The facilities are such that there is no good reason why physicians should not buy their thermometers furnished with the Yale Certificate by the dealers; in those cases where no certificate is furnished the uncertainty may amount to two degrees. It should be remembered that thermometers which the physician has had in his possession for many months are certain to have had the requisite seasoning, and therefore an old thermometer with a recent certificate is more

valuable than a new one, or one about whose age there is doubt.

The Observatory has been called upon within three months to certify about seven hundred thermometers from various parts of our country; the results of this work have demonstrated the gross inaccuracy of the cheaper clinical thermometers as commonly sold, and seem to render expedient the publication of this card calling the attention of physicians to these errors and the great difficulty of detecting them except with the appliances of an Observatory devoted to this work.

LEONARD WALDO,
Astronomer in Charge.

New Haven, Conn., February 1st, 1881.

Circulars with further particulars can be had by addressing Professor Waldo.

To insure the safe transmission of thermometers by express, they should be packed in two boxes, one inside the other, and the space filled with cotton-wool or its equivalent. Single clinical thermometers may be packed in wooden boxes and sent by mail. New York makers desiring to send thermometers by hand may do so by leaving them with Lockwood's private express, care Œlschlæger Bros., 162 William Street. The P. O. Address of the Observatory is Box 853. The office is at 89 Orange Street, to which all packages may be directed.

Pharmacy vs. Medicine.

A committee of the Board of Trustees of the College of Pharmacy, of this city, lately made the following report:—

The committee appointed to meet in conference a committee of the Philadelphia County Medical Society, by request of said committee of the County Medical Society, to discuss some plan of proceeding to regulate the evil claimed to exist in reference to, 1st, "the renewal of physicians' prescriptions;" 2d, "prescribing by druggists;" 3d, "the sale of proprietary medicines;" 4th, "ordering by physicians of special formulas;" 5th, "the adoption of such additions to the medical and pharmaceutical codes of ethics now existing as will tend to advance the professional rights of the physician and pharmacist in Philadelphia, and maintain mutual respect and consideration of the two professions without ignoring the short-comings of either"—

Respectfully report that a meeting of the two committees was held at the rooms of the County Medical Society, Dec. 10th last.

After a general discussion, embracing the merits of the *whole* subject, the divisions of the subject, as detailed above, were taken up *seriatim*.

It was the general impression regarding the vexed question of *ownership* in a prescription, that the decision of a case by a court of competent jurisdiction could alone settle the question to the satisfaction of all concerned; but that, in the absence of a statute law on the subject in Pennsylvania, the long continued custom of regarding the prescription as the property of the patient could not be disregarded. It was also brought to the notice of the medical profession that it would be difficult to prevent the holder of a prescription from obtaining a copy of the same, and that a *renewal* of the prescription could not be prevented by a decision of ownership adverse to the holder of the *original*. It was therefore the judgment of the joint committee that when physicians desired their prescriptions not to be renewed they should make such a request on the prescription, and, if printed, to sign their name under the *printed* form, to give greater weight to the request.

It was also the judgment of the committee that physicians should instruct their patients regarding the evils which sometimes occur in consequence of continuing a prescription beyond the time intended, without further medical advice being obtained.

"Prescribing by druggists," except in cases of trivial ailments, or where the necessity of the case demanded relief before a physician could be called, was unanimously condemned. The code of ethics of the Philadelphia College of Pharmacy on this subject was read, and, in the judgment of the committee, covered acceptably the question. The code is as follows:—

"Sec. 2d. As the diagnosis and treatment of disease belong to the province of a distinct profession, and as a pharmaceutical education does not qualify the graduate for these responsible offices, we should, where it is practicable, refer applicants for medical aid to a regular physician."

"The sale of proprietary medicines." Here, also, the code of ethics of the Philadelphia College of Pharmacy was found to be satisfactory, as follows:—

"While the College does not feel at present authorized to require its members to abandon the sale of secret or quack medicines, it earnestly recommends the propriety of discouraging their employment, when called upon for an opinion as to their merits."

"The ordering by physicians of special formulas." The practice of writing prescriptions so as to be understood by some one or two pharmacists alone was stated to be a violation of the ethics of the County Medical Society, and was condemned as unprofessional.

The committee agreed to recommend to the County Medical Society and to the Philadelphia College of Pharmacy that greater publicity among physicians and pharmacists should be given to the codes of ethics of both of these bodies, as tending the better to define the position of the two professions to each other.

The meeting was marked by a pleasant cordiality of feeling, and a mutual desire for a full recognition of the rights of each profession, and the maintenance of a mutual respect and consideration.

New England Agency.

Our New England Agent, Mr. D. M. Rice, No. 5 Madison Park Hotel, Boston, Mass., has made arrangements with Messrs HALL & WHITING, Booksellers and Stationers, 32 Bromfield street, Boston, who will keep a full stock of our Publications, and will be able at all times to fill orders promptly and at same terms as heretofore. Physicians and dealers residing in New England will please favor them with their orders.

Items

Correction.—Dr. Christine writes, in reference to his case of a curious affection of the Nails (p. 163):—

"The work in which the patient was engaged was of a *non*-poisonous character. Had her work been of a poisonous nature, I should have had in this a clue to the cause. But its freedom from anything of the kind renders the solution difficult."

—Charles Sumner, Mr. Z. L. White says, did not know what dyspepsia was. Speaking of his good fortune in this respect, one evening, he said that one of the first requisites to success in political life was a good digestion, and he reminded his visitor that a majority of the Senators were portly men. While he admitted that slim, dyspeptic men sometimes attained high position, still he maintained that in order to do so they had to overcome greater obstacles than those who had good stomachs.

—There were 976 deaths in Chicago last month, against 771 in January, 1880, and 664 in January, 1879. Among the deaths last month eighteen were from smallpox, eighty-six from diphtheria, fifty-seven from croup, and thirty-seven "through violence."

OBITUARY NOTICES.

—Dr. W. H. Baird, of Saline county, Ark., met his death suddenly by the caving in of the sides of a well, which he was having dug. He was thirty five years of age, and leaves a wife and family.

—Ebenezer Alden, M.D., one of the oldest citizens of Randolph, Mass., his native town, died on Wednesday, January 26th, being almost ninety-three years of age. He was born March 17th, 1788; was graduated from Harvard College in 1808; pursued his professional studies with Nathan Smith, M.D., at Dartmouth College, where he received the degree of M.B. in 1811; attended the lectures of Drs. Rush, Barton and others, in Philadelphia, and received the degree of M.D. from the University of Pennsylvania in 1812. He settled as physician in his native town, where he has resided during his entire life. He was laboriously devoted to his profession, and was well known for many years as one of the leading physicians and surgeons of Norfolk county.

QUERIES AND REPLIES.

Ethics.

Mr. Editor.—Dr. A. is treating a case. Some time after, Dr. B. is called to see the case in consultation with Dr. A. Afterward, by the friends of the patient, Dr. C. is sent for, without the assent of Drs. A. or B. But before Dr. C. arrives, Dr. A. is informed of the fact, and expresses his willingness to consult with Dr. C. Dr. C. arrives, and is requested by the friends of the patient to take charge of the case. Dr. C. replies that he cannot do so without a consultation with Dr. A., or unless Dr. A. is discharged; thereupon Dr. A is discharged, and Dr. C. takes the case.

Question:—Did Dr. C. act in accordance with the Code of Medical Ethics, or did he not? F. H. B., Ohio.

Ans.—As the case was first visited by Dr. A., Dr. C. should not have suggested his discharge, unless Dr. A. had refused to consult with him.

Calomel and Chlorate of Potash.

Ed. Reporter.—I notice, in your issue of January 29th, the Query of J.G., Jr., of Ala. "Will not chlorate of potash and calomel, when given together, form the bichloride of mercury? Also your reply. I recently met with a case which I think will warrant me in assuming the affirmative of the question clinically.

C.W., aged four years, suffering from an attack of pharyngitis (acute). I ordered a purgative dose of calomel, and at the same time a prescription containing tinctura ferri chloridi, and potass. chlorat. The latter not to be given until the purgative effects of the former had been obtained. But, contrary to my directions, in about one hour after giving the calomel they gave a dose of the iron and potash.

A short time subsequently I was summoned, and found my little patient suffering from all the symptoms of poisoning by corrosive sublimate, but with no salivation, nor did any appear subsequently. I administered the usual remedies for such poisoning, and the recovery was rapid. H. W., Ohio.

Mr. Editor.—Can any of your numerous readers give me the weight of the brain of the murderer Ruloff, who was executed at Binghamton, New York, some ten years since. It was asserted here to be the heaviest brain on record, and I contradicted it. Want to know if I was right, as I find no record of it in any of my works. T. A. B., of Pa.

MARRIAGES.

AMERMAN—LATTIMORE.—At New Boston, Schuylkill county, Pa., January 25th, by the Rev. A.M. Woods, A. Amerman, M.D., of Danville, Pa., and Carrie A. Lattimore, of New Boston.

JOHNSON—BAKER.—At Mr. Isaac Taylor's, the bride's home, January 18th, 1881, by the Rev. W. M. Taylor, assisted by the Rev. William Memminger, Mr. William H. Johnston, M.D., and Mrs. M. T. Baker, sister of the officiating clergyman, all of Huntingdon county, Pa.

MILLER—GAINES.—On Thursday, January 20th, 1881, at the residence of the bride's parents, Geneseo, Ill., Robert W. Miller, M.D., of Guthrie, Iowa, and Lucy A. Gaines, youngest daughter of Nelson Gaines, Esq.

DEATHS.

BELVILLE.—At Dayton, Ohio, on January 26th, Jacob Belville, M.D., aged seventy years. He was born at Newcastle, Del., in 1811.

CARSON.—At his residence, in Leechburg, Pa., January 7th, 1881, of malignant diphtheria, John Allingham Carson, M.D., in the thirty-first year of his age.

STEARNS.—At Elizabeth, N. J., February 2d, 1881, Josiah Q. Stearns, M.D., in the sixty-eighth year of his age.

TOWER.—At his residence, 295 Richmond street, Cincinnati, Ohio, on January 27th, at 5 P.M., Dr. E. C. Tower, of paralysis, aged sixty-six years.

WINTERBURN.—In New York, suddenly, January 23d, Charles Winterburn, M.D., formerly of Yorkshire, England.

WOODRUFF.—In this city, January 31st, Dr. A. Dickinson Woodruff, aged sixty-two years.

J. C. BAKER & CO'S COD-LIVER OIL.

Absolute Purity and Freshness

Secured by Specifying our Brand.

Prepared on the **HALTEN ISLANDS, NORWAY**, with great care, from the finest selected livers of **NET-TAKEN COD FISH**, at a season of the year when they are in their highest condition.

PRIZE MEDAL—PARIS, 1878; BERLIN, 1880

BAKER'S EMULSION

With Hypophosphites of Lime and Soda, containing fifty per cent. Pure Oil, is a perfect and potent preparation.

☞ We employ Baker's Cod-liver Oil in preference to all others. The Pure Oil is palatable and digestible, and the Emulsion is well nigh delightful.

Agents for Barlett's Pile Suppositories.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

ENDOCARDITIS, OR VALVULAR DISEASES.

BY ALONZO CLARK, M.D., LL.D.,

President and Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons, New York.

(*Continued from page* 34).

We will continue the subject of diseases of the valves of the heart. I had explained to you that endocarditis is perhaps the most prolific cause of derangement of the valves, and that it may occur as the result of acute disease, commonly associated with rheumatism, occasionally found in connection with Bright's disease, sometimes occurring in the course of measles, and rather frequently in the dropsical sequelæ of scarlet fever; then, too, sometimes occurring in septicæmia. And still again, I told you it may occur independently of any of these causes—a spontaneous, I might say almost idiopathic disease. That it does occur frequently in this manner is rendered evident by the large number of persons that suffer from disease of the valves who have not had any serious sickness preceding the development of heart disease; who have not had rheumatism; who do not remember that they have had scarlet fever; who have not had Bright's disease, etc. Then I told you of atheroma, a particular deposit, more frequently found on the inner, or rather under the inner, lining of the arteries, encroaching upon the elastic tissues of the walls. I told you that it undergoes, whether in the valves here or in the artery, one of two changes, as a rule. It may soften and form a yellow collection, looking like an abscess, and this may rupture the intima, and escape into the blood, and do mischief or not, according to the fineness of its division. The other change is to a calcareous matter, a calcareous degeneration of the arteries or valves of the heart, having been preceded by atheroma. It does not seem possible that the elements of an atheroma can be converted into a bony matter. It would seem altogether likely, therefore, that it is substituted for these after they are softened and have been absorbed. I told you that this deposit in the valves causes a thickening of them, an inflammation of them, a bony deposit especially being a constant irritation. I told you that the valves are sometimes ruptured; and I pointed out to you a specimen in which the inferior or lower portion had given way, so as to render that part of the valve useless in retaining the blood in the artery. I told you of a case—I don't know, though, whether I did—a case in which a man, lifting a heavy beam—he was a foreman in a cotton mill and some heavy beam connected with the machinery had fallen, or one end of it had fallen, and he with some other men attempted to raise it to its place—and while doing this he felt a sudden something, he could hardly tell what; but he said there was something that gave way, and he fainted and sat for a considerable time in the mill before he attempted to go home, and then went home with assistance; in a few days he revived again and went to his work. He lived twelve years after that, and had a very large hypertrophy. At post-mortem the longest portion of the tricuspid valve was seen to have been flapping backward and forward in the current of blood. As the blood ran down the strand was in the ventricle, and when the heart contracted it would

double back on the rest of the valve. A tendinous cord had given way, and he felt a sensation of something giving way. There was a murmur heard in systole, not in diastole.

The valve may give way in a considerable variety of cases. A gardener had loaded his cart too heavily; his horse could not draw it, and he put his shoulder to the rear of it, to help the horse, and exerting about all his strength he also felt something give way, and was very much crippled after that. He came to Bellevue Hospital; there I had an opportunity of examining him before and after death. A portion of one of the folds of the aortic valve had given way in his case, and I thought almost without previous disease of it. Atheroma is a very common precedent of the breaking of valves. This man lived about two years after the accident occurred to him; the other seven.

I was with a gentleman who was making great haste to reach the top of a hill. He was within about fifty feet of it, and he started on a run up the steep acclivity. The result was, he was brought into the same condition as the gardener, and from that time on, as long as I knew him, there was a regurgitant murmur at the aortic opening. He broke something at that time. Precisely what, whether the bottom of the valve gave way, or whether it split down, I cannot tell. One thing, however, with regard to the splitting of a valve, that is worthy of notice. You remember there is on the top of the valve a kind of cord, and immediately below that cord the valve is not as strong as at the edge. The common way for a valve to break is to give way at that cord, and it vibrates in the current of blood, and frequently makes a musical sound, a sort of Æolian harp sound; making a noise that is not altogether unlike that of a cord stretched across a little opening in a window. It is quite a musical note, and I don't know that there are any other circumstances in which that musical sound is produced. Then I should add, in this enumeration, that the tendinous cords are occasionally found welded together, two, or three, or more of them, and, of course, a great deal crippled in their action. In certain instances the two folds of the mitral valve and the three portions of the aortic valve grow together, in the latter case leaving a slit by which the blood can go out and by which it will return in regurgitation. How in the world that can occur I do not know, but it does occur. They are almost always thickened, so that they do not play freely before this adhesion or coalescence takes place. But moved, as they are, continuously, by the current and reflux of blood, it is very difficult to understand how these three portions of the aortic valve can grow together, leaving only a little slit for the blood to pass through. It is easier to understand how adhesion may take place between the two curtains of the mitral valve, for by contraction they can be drawn together, and contraction is effected by the material that is deposited between the two folds of the valve.

I will put in your hands, now, for example, a few specimens of valvular disease. Here is one, for example, in which, as you open it in this way, the wall is the seat of spots of atheroma, and some of these have passed into a calcareous condition, just here, near the valve. Even the valve itself is shortened and thickened, but not remarkably. Now, here is the aortic valve, that is very much diseased. If you put your finger on it you will find that it has hard scales on it. It is not very much contracted, except one fold of it. One fold is thickened and hardened, and on the inside of it is a little calcareous matter. This has been a pericarditis, and the outside of it is roughened by the adhesions that formerly existed on the pericardium. The mitral valve is in a state of very marked stenosis, that is, contracted, and you see here almost nothing of the tendinous cords—they are shortened so much. The fleshy columns are a little elongated, to make compensation for that shortening of the tendinous cords. This is a pretty striking specimen of stenosis of the mitral valve, and in this connection it may be that we shall find an illustration of the rule that applies to such cases generally, that is, stenosis of the mitral valve induces hypertrophy of the right ventricle; stenosis of the left auriculo-ventricular valve induces hypertrophy of the right ventricle, and frequently of the right auricle, and also sometimes of the left auricle. This you see illustrated here. It is thicker than natural, the right ventricle, but not very much hypertrophied. This stenosis, marked as it is, did not disturb the circulation as the same lesion does sometimes. Then in this specimen you have two lesions, the aortic valves thickened and a little calcareous deposit in them; at the mitral valves, stenosis.

In this specimen the mitral valve is thickened and hard, but not disorganized, and it is large enough to allow the circulation to go on with ordinary freedom. The aortic valves are thickened, shortened, and hardened.

In this specimen the aortic valves are a little but not much diseased. The chief lesion is probably in the mitral. You observe the mitral valve is thickened, not exactly disorganized. There is some hypertrophy of the heart. This is not a very striking specimen.

Here is a very good one, and opened in such a way that you can see the change that has taken place; it is in the aortic valve. You observe they are contracted in their length, contracted in height, and thickened, but not nearly as much as in some specimens I shall show you hereafter.

Now comes the question, what sort of disturbance will these lesions of the valves produce. Of course, it will be first felt in the circulation. Let us take a mitral stenosis, such as you have in two or three of the specimens now going round, and its effects are perhaps as simple as the effects of any of these lesions. Indeed, they all follow pretty nearly in the same track after they have taken the first step. Remember, now, that the blood in the left auricle has just come from the lungs, and it is seeking its way into the left ventricle. It is obstructed at the valves; well, what will that do? The circulation by the right heart we are to assume is natural. The blood goes into the general system, and empties into the right side of the heart, and from that is thrown into the lungs, and it begins to come from the lungs into the left heart and is obstructed; what then? The first thing will be a certain amount of engorgement of the lungs. They receive blood faster than they can discharge it; the consequence is, therefore, an engorgement of the lungs, greater or less, depending upon the extent of the stenosis. Next after that comes a strain upon the right heart, which is attempting to send blood all the time into the lungs, and associated with this may be what is called an emphasized condition of the second sound in the pulmonary artery. That is pretty full of blood, the right heart pumps more into it, the reaction is stronger, and makes the valves strike with more force than natural. Hence, an increase in the second sound in the pulmonary artery, in an instance where the disease is at all considerable. Well, what more? Stop the blood from coming into the right heart and what will be flooded? Why, every important organ of the body. The blood cannot return from the veins with anything like its natural freedom. The liver will be engorged, the spleen will be engorged, the brain will contain more blood than it should, the face perhaps will be a little puffy, from a little effusion into the tissues from the veins. The veins cannot empty themselves freely. Little clusters of enlarged veins are found upon the surface of the body, chiefly upon the chest. The external thoracic veins frequently become enlarged. There is general hindrance of the blood in the general circulation, because there is obstruction of the blood in the lungs, and consequently obstruction in the right heart, to which the blood in the general system should naturally go. One consequence of this accident, then, is enlargement of the liver; not in all cases, not in the majority of cases, but now and then. And sometimes quite considerable hypertrophy of the heart, and enlargement of the spleen, from the same cause, namely, obstructed return of blood. The effect upon the stomach is often noticeable. There being more blood in the stomach mucous membrane, the digestive membrane, than can be used, the digestion becomes impaired. It is imperfect, and the appetite feels the effect of that. Then, too, the effect of the obstruction is sometimes so considerable as to hinder the contribution of the thoracic duct to the general nutrition of the body. The thoracic duct, you remember, receives the material that is digested in the intestine, and carries it to a vein, through a duct, and that vein delivers it to the general circulation. Well, that is obstructed also; it cannot freely give its nutritious fluid to the blood, and it not infrequently happens that the patient becomes pale, in consequence of imperfect nourishment, though he may eat a considerable quantity of food; and you will observe, frequently—I am referring now to an advanced case—that the patient speaks of his feet being swelled, particularly at night, if he is on his feet during the day, and you observe yourself some puffiness about the face. You will particularly be able to notice what has been called the tear line; that is, a something looking like a silver thread or a thread of transparent glass lying upon the upper edge of the lower eyelid. It is a little œdema of the conjunctival covering, and as the eyelid presses considerably upon the eye it is forced up along the ridge, above the tear line. There may not only be œdema of different parts of the body, but the whole body may be swollen. The kidneys have suffered congestion, and have taken on a condition analogous to that of Bright's disease, generally the large white kidney, and they are unable to perform their function properly. The urea remains in the blood, or a part of it, at any rate, and produces its general effects. The urine is commonly scanty, sometimes even bloody, and then again there is not unfrequently an effusion found in the chest, a double pleuritic effusion. Day before yesterday I examined a gentleman from the country, or rather from a distant city, who had been ill for some months, and in the course of the examination found fluid effusion coming nearly up to the lower angle of the scapula on both sides. My thought was, he has Bright's disease. He had heart disease, for his

heart was enlarged, but there was no valvular murmur at the time I examined him. On examining the water I found it contained a large quantity of albumen. It was one of the cases that interested the late Dr. Stephens so much when this matter was first investigated. There was a good deal of the amorphous urates in the urine, and they settled slowly. Putting the urine charged with the amorphous urates into a test tube it was almost opaque; on heating it, it became perfectly transparent, but heating it more, up to about the point of boiling, it became cloudy with albumen, and heating it till it boiled, it became almost thick. I have a scale for estimating the amount of albumen in the urine, ranging from one to ten. Ten represents a coagulation of albumen in the tube, so that nothing will run out; invert the tube and nothing is discharged; the whole of the urine is imprisoned in the coagulated albumen. When there is but a trace of albumen it is represented by one. In the specimen of the patient spoken of the amount of albumen was represented by six; or more than half of the urine was composed of albumen. I did not know that this gentleman had Bright's disease when I found a double pleuritic effusion (although I felt pretty sure of it), for double pleuritic effusion does once in a while occur without Bright's disease.

This, then, is substantially the series of consequences that will result from obstruction, from stenosis of the mitral valve. And you can see that when the blood is returned through this valve, that is, when it has entered the ventricle and a part of it is returned into the auricle, that is going to do exactly the same thing when the condition becomes marked. It is all the same, save that that was stenosis, this is insufficiency. The valve is incapable of serving as a gate, a watch, and a part of the blood that enters the ventricle goes back into the left auricle, and obstructs the blood that would come in from the lung, so that the result in the end is exactly the same, congestion of these various parts, sometimes cyanosis. This latter belongs also to mitral stenosis.

Then there is another point which I may as well refer to here. You sometimes see a pulsation in the veins of the neck, the jugular. There are two modes in which what appears a little like a pulsation is to be accounted for. When this obstructed circulation occurs the vein is seen to fill in expiration. In expiration the blood does not flow so freely in the lungs or into the chest, as in inspiration, and in expiration you may watch the vein and see it fill, but it fills from above. It is not a wave coming up from below. About the only conditions in which the wave will come up from below are, when there are insufficiency of the tricuspid valve, that is, the valve of the right side of the heart, or when there is hypertrophy of the right auricle, or when there is a pulsation tumor, like an aneurism resting upon the vena cava descendens. In either of these cases a regular wave may come up the vein, but I know of no other condition in which it does occur; but in the cases referred to you observe the filling of the vein is a different thing from a wave coming from the heart, or a pulsation from an aneurismal tumor. It is not necessary to dwell longer upon the regurgitation at the mitral valve, as the effects of it in the end are the same as those of stenosis.

Now turn to the aortic valve, to the two conditions that have been named, obstructive disease and regurgitative, or direct and indirect, if you choose to so call it. When there is obstruction at the aortic valve the sound produced by it will be heard in the contraction of the heart in systole, and it will be loudest at the base of the heart, near the sternum. That may exist in moderate degree for a very long time, and no very grave consequences result. But if it is a growing disease, if it is a form of valvular disease that is irritating in itself, like a spicula of calcareous matter in the valve, action of the valve will excite an inflammation and cause a deposit of material that can contract and still further deform the valve. But there are a great many persons who can carry both mitral regurgitation and aortic obstruction a very long term of years. Indeed, my colleague, the late Dr. Gilman, came to me with mitral disease, at a certain time, and he said, "am I going to die of it?" "Well, maybe." "Well, when?" "O, I think you will live twenty years." The years rolled on, and I heard nothing more of it until, at length, Dr. G. came to my house, and exclaimed, "There, doctor my lease is out! I want to renew it!" He lived about four years after that.

I remember a patient who carried a valvular lesion fifty years before a fatal sickness occurred; a young man, at first, all activity, but, of course, he could not go up-hill or up-stairs as well as other people, but his mind was active, and as an evidence of his industry, in the old time, when speculation did not fill a man's pocket in a day, he had made by whale oil a million of dollars, and built up the fortunes of two brothers in this period of fifty years.

I am in the habit of referring to a certain case because it is rather impressive. Many

years ago I had occasion to listen over a certain gentleman's heart, and I found a mitral murmur. He appeared perfectly well, and I went on, made no sign of surprise, and I thought the thing over. He is of phlegmatic temperament, and I do not think he will be very much excited; he will take the world pretty easy; I think he will take the world quite as easy without as with a knowledge of the disease of his heart. Now that gentleman is in active practice to-day; you see his name not infrequently in the medical journals, as having performed this or that operation, and he is a great deal happier than he would be if he knew he had mitral regurgitation. There is no knowing, then, when the unfavorable issue will take place; but I can tell you this about it: when a patient comes to you complaining of a great deal of shortness of breath, when he has œdema of the feet, and possibly some swelling of the face, look to the kidneys. They probably have become involved by that time, and in a few weeks, in a week or two, he may be pretty gravely sick, having carried disease of the heart for twenty, thirty, forty, or possibly fifty years, as in the case I have just referred to. And here it is perhaps proper to say that the last generation of doctors and the present generation of people who are not doctors look upon the statement that they have heart disease as equivalent to signing their death warrant. The profession have outgrown the idea that heart disease must be fatal in a few months; but the older physicians, physicians of past generations, not having auscultation to guide them, were not able to detect diseases of the heart until they came to involve disease of the kidneys, and perhaps of the liver, and possibly of the spleen. In other words, not until œdema came. Their post-mortem examinations told them what that meant. They were able to recognize then, by the general signs, what was the trouble, but the patients generally died pretty soon, in a few months after the œdema occurred. But they may have passed forty, fifty, or even sixty years before that, with the same disease of the heart, only it now comes to be obstructive to the venous circulation.

But to go on with the obstruction at the aortic opening. If it is moderate there is compensation. The heart has the faculty of growing in size and in strength to meet an emergency, and we speak of compensating hypertrophy of the heart. If the blood does not flow easily through the aortic opening the heart will gain additional strength by gaining additional fibres, and will overcome the obstacle, so that a man may carry a disease of that kind a great while without knowing that he has it. But when regurgitation occurs, and that is only in the advanced stages of obstructive disease, when the valves become shortened and thickened, so that they cannot fall together, a certain quantity of blood that has been sent into the aorta goes back again into the ventricle every time the heart dilates, and here is work to be done over and over again. The heart has to do its work twice over, substantially, at any rate, once and a half. The ventricle has just been filled from blood forced in from the auricle, and half filled from that that comes from the aorta. The effect of that is exactly that which I have been describing to you, and you will see how it must be so. When blood from the aorta falls back into the left ventricle it prevents blood from coming in from the left auricle. Only about half the contents of the ventricles can come in from the left auricle, and consequently the blood will set back upon the right heart, and engorge the lungs, and it will also produce very much the same general symptoms that I have described to you. Well, then, these all come to about the same thing. Regurgitation by the aortic valve, regurgitation by the mitral valve, are only one step apart, and their consequences are substantially the same. So also contraction of the mitral wave. A contraction of the aortic valve, you observe, is compensated for very generally, and that is not so grave a trouble. A stronger current of blood is sent over it, and, of course, into the general circulation more blood is sent in a given time, and consequently the general circulation does not feel it so much. These are the general effects relating to the advanced stage of cardiac disease.

The question has been often raised and discussed, which comes first, the kidney disease or the cardiac disease. My own answer is very positive; that while the cardiac disease may come after the kidney affection has begun, in the great majority of instances in which they are connected, the connection is as I have been describing to you. The kidneys become congested because the circulation is obstructed at the heart, and after they have suffered a certain length of time they will begin to give albuminous urine; they do not secrete the urea in full measure, and œdema then begins in different parts of the body. It is my strong conviction that in nine cases out of ten where the two are associated the cardiac disease preceded, and the others will be instances in which kidney disease from some other cause has occurred, and the cardiac disease has followed it, possibly by the influence of congestion in a certain degree. But the order is almost always

cardiac disease first, and renal disease afterward. I have noticed so often what I have already explained to you that I cannot have a doubt about it. I examine a man and find he has valvular lesion of one sort or another; I watch him for a year; he gets along very well; and perhaps ten, fifteen, or twenty years after I had examined him for the first time he begins to suffer; he begins to get œdema of the lung, which is one of the effects I have not mentioned—œdematous condition of the lungs, as well as of the legs, body, and face.

With reference to the right side of the heart: we have but little experience with disease of the valves on this side. For forty-nine cases of valvular disease of the left heart there will hardly be one of valvular disease of the right heart. I have told you that after birth the left side of the heart is the seat of disease, and before birth the right. In the right heart there are lesions of the valves, though rarely met with. In a little boy about eight years old, when the college was in Crosby street, I found a very peculiar sound in listening over the base of the heart. It was not a murmur, but it was a snap, and it was in both actions of the heart. It was a double snap, very much such as you get by pulling a piece of ribbon suddenly. He died, and at the post-mortem examination, that sealing together of the pulmonary valves was found which I have already described to you. The edges of the three portions of the valve were sealed together, with the exception of an opening, which must have been less than half an inch in the middle, and one of the lips of that opening was a little longer than the other, and it was that that snapped when the blood came against it from the heart, and snapped again when the presure from the artery was felt. That was the only lesion about it. I did not distinguish that from aortic disease, for it is a difficult thing to do it, but some persons claim to be able to do so by getting the sounds of the pulmonary valves a little to the left of the sounds that come from the aorta. I dare not trust my ear for the diagnosis; and besides, there is another mode that is worth something, and not worth a great deal either, and that is, if the sound is at the base of the heart, to follow it to the artery, and particularly to the left and right clavicle. Listen to the sound from the heart there; if it comes up there pretty fully, it is in all probability in the aorta. I say, in all probability. I make that modification because the two vessels, the pulmonary artery and the aorta, are sealed together by loose connective tissue, and for a certain distance after they leave the heart they run together.

Communications.

CHRONIC NASAL CATARRH.

BY JOHN W. GUSTINE, M.D.,
Of Carroll, Iowa.

Read before the Central District Medical Association, of Iowa, December 21st, 1880.

My principal object in writing this paper is to excite an interest, if possible, in a disease which is certainly as prevalent in the west, if not more common, than any other morbid affection to which our population is subject. Iowa especially may be termed an ozæna State. It may be said to be almost indigenous to her population, the proportion being about one in three.

Authors have assigned various causes of this disease, and what few have written upon its nature and cause differ, and leave us in as much doubt as to what really produces it as we were before we read their views.

Dr. Allen,* Prof. of Physiology in the University of Pennsylvania, gives a very unique and ingenious cause for this affection; he says, "The nasal chamber being a modified portion of the respiratory tract, it follows that its functional integrity is dependent upon the freedom with which a current of air can pass through it. Obstruction is fatal to its efficiency, for not only is the sense of smelling lost, but the unconscious effort to breathe through the nose ordinarily causes congestion and distress, and at all times the normal outflow and distribution of mucus is interfered with. Nasal mucus has a tendency to flow backward. The gentle inclination of the floor of the nose from before backward and the dip of the turbinated bones determine this. Nasal obstruction interrupts this flow, and occasions accumulation and subsequent inspissation of mucus, or a reversal of the current, which results in escape of the secretion at the nostrils." He also claims that in most instances this obstruction is produced by the bones of the nose impinging on the soft parts, not by slight, but with firm pressure. He further says that there are "a variously defined group of cases encountered, in which the nasal chambers are everywhere capacious and yield nowhere any abnormal contact. These are probably instances, when not local expressions of constitutional conditions, due to rhinitis fluxes, the result of structural changes in the membrane itself, or the sequence of imperfectly guarded chambers, which permit the too free ingress of irritating

* *American Journal of the Medical Sciences* or January, 1880.

currents of air, and thus the membranes are continually exposed to the contact of extraneous substances, and to abrupt changes in temperature." Prof. Allen does not exclude other causes as operating to produce this disease, but contends that this is one of the principal causes.

Prof. Samuel D. Gross, in his *System of Surgery*, gives it as his opinion that ozæna is produced, in most if not all instances, by a scrofulous diathesis or a contamination of the system with syphilitic virus. Admitting this to be the fact, that these two causes are the main factors in producing this disease, we would be loth to concede that one third of our population have either inherited morbific elements destructive to the vigorous health of our citizens, or acquired demoralizing vices, which would leave them but human wrecks; that we are either syphilitic debauchers or strumous descendants. Niemeyer, in my opinion, comes nearer to the true etiology of this disease than most of those who have written on it. He believes it to commence with cold in the head, local irritants, such as the entrance of hot air, dust, acrid gases, or foreign bodies, the snuffing of tobacco by persons unaccustomed to its use, blows, shocks, etc. He also alludes to the strumous and syphilitic taint. These latter, no doubt, have a tendency to disseminate the malady and increase its inveteracy. But these causes are insufficient to explain why this disease is so prevalent in the West; why so many persons of apparently good, sound constitutions, should be afflicted with it for years, and some even for a lifetime.

If we examine the anatomical parts involved, we find an extensive surface lined with one of the most sensitive and vascular membranes in the human body. The Schneiderian membrane is one of extreme vascularity; it is also furnished with a large number of nerves and nerve filaments, the blood vessels having a very superficial course, rendering it very sensitive to changes in the temperature and to the deleterious effects of foreign bodies. Underlying it, in some parts, are the most delicate and thin plates of bone, and filled with cells, which are met with in the osseous system. This membrane is also composed of mucous glands, which pour forth a white, transparent, inodorous and insipid fluid; liable to undergo various changes, such as irritation, congestion, inflammation, ulceration, gangrene, polypi, schirrus, cancer, atrophy and hypertrophy. Guarding the entrance to the organs of respiration, exposed to the first impressions of all noxious as well as innoxious emanations, it is strange that it should be equally if not more predisposed to morbific action than other parts of the human system. If noxious effluvia are impressed upon it, congestion follows, even though evanescent in its effects; cold also produces the same condition; after the irritant passes off, it returns to the normal state, and hence these continual wavelets of repose and reaction in its vascularity must, of a consequence, eventually produce disease.

Microscopical investigation has done scarcely anything towards elucidating the cause of this affection, neither has pathological anatomy contributed anything towards arriving at a correct conclusion; for the opportunity seldom presents itself to take observations on the cadaver, therefore we are compelled to reason, to a great extent, from analogy, to assist us in determining what may be the etiology of this disease, even though our conclusions may be based somewhat on hypothesis.

Wherever the temperature falls below the freezing point, we find chronic nasal catarrh co-extensive with this condition of the atmosphere. Its prevalence and frequency depends much upon this thermal line. In warm latitudes you scarcely ever find a case of this disease, unless imported. Removal to a warm climate is more certain to benefit this class of patients than all the remedies yet discovered. The more variable and cold the climate, the more frequent are its subjects. Might not the sudden extremes of heat and cold incident to our climate, acting on a sensitive membrane like the mucous tissue of the nose, driving the blood from the external surface to the internal, and then in a short time followed by reaction, keeping up diminutive waves of excitement and depression, be one of the great sources of this disease? We find our population afflicted six or eight months in the year with all forms of cold in the head, from a highly congested condition of the Schneiderian membrane down to various shades of vascular excitement. Continuous attacks of this kind for months and years must cause disease of this organ in the end. There is no truth better established in pathology than this fact, that frequent acute or lengthy attacks of morbid action in any tissue is followed by a chronic state, unless its violence destroys the part. If this position be true, are we not warranted in supposing ozæna, in this climate, due to this cause? Why may there not be some unseen and peculiar condition of the atmosphere in localities producing this affection, as well as those causing malaria and goitre in the mountainous districts of Europe. An objection may be raised to this line of argument, that in many

individuals laboring under this disease only one of the nasal passages is involved. Why not both in all subjects? If Prof. Allen's investigations are correct, that "out of fifty-eight skulls preserved in the Wistar and Homer Museum only eighteen exhibited normal nasal chambers; in the remaining thirty-seven, nineteen were narrowed on the left side and twenty-one on the right;" this goes far to explain why one nostril is more frequently affected than both.

According to Rokitansky, this disease gives rise "to polypous outgrowths, which appear first as a diffuse thickening over a large surface of the mucous membrane, particularly on the turbinated bones, growing with an uneven surface, and developing wart-like protuberances and fold-like ridges. Sometimes the growths are more circumscribed, assuming a rounded, pedunculated, pyriform shape. They consist of a gelatinous growth from the matrix of connective tissue of the mucous membrane and from its glands, which frequently degenerates into cysts. Gradually the material of which the growths are constituted is converted into firm fibrous tissue. They contract or block up the air-passages, and finally may become visible in the openings of the nostrils."

There is another fact, so patent to the pathologis that it would be an oversight not to refer to it. It is this: that we have diseases analogous to chronic nasal catarrh, involving the mucous membrane lining other organs, which to a great extent present similar symptoms, course and termination, resisting, in numerous cases, any rational plan of treatment. Follicular inflammation of the throat, chronic bronchitis, catarrh of the stomach, chronic inflammation of the mucous membrane of the bowels, catarrh of the bladder, leucorrhœa, chronic endo-metritis, chronic endo-cervicitis, are some of those morbid affections which present a number of features similar to the disease under discussion. In the affections invading the mucous membrane of these organs above mentioned, which are of a chronic character, we have the turgescence, increased flow of mucus, or muco-purulent secretion. We have in some of them the same intractibility, the same futility of treatment; the diseases resisting often our best directed efforts, running on for years without any amelioration; teachers advising the most opposite plans of treatment; the remedial measures differing as much as their effects are various.

The inference to be drawn from these facts is, that less is known about the successful treatment of the chronic complaints of mucous membrane than any other diseased tissue of the body. This inference is certainly true with respect to chronic nasal catarrh.

The causes enumerated by those who have written on this subject are insufficient to explain why so many persons are affected in this latitude; we are therefore compelled to seek some other predisposing cause, and that cause we believe to be a peculiarity of our western climate. True it is that some persons are more susceptible to its influence than others, especially those who are subject to irritable and granular throats, chronic enlargement of the tonsils, those who snore in their sleep, and are of a lymphatic temperament. Individuals who are susceptible, as many are in this cold, variable climate, to frequent attacks of coryza or acute colds in the head, are most afflicted with ozæna.

This disease may involve a large portion of the lining membrane of the nose, or it may be confined to a locality. It may affect the turbinated bones, the middle and inferior meati, the floor of the nostrils, the soft palate and the pharynx, the superior maxillary and frontal sinuses, and even extend to the ethmoidal cells.

Mere chronic congestion may alone be present for a long time, with increased flow of mucus or muco-purulent matter. If the diseased action continues and the morbid secretion becomes obstructed, large flakes of inspissated matter are thrown off, some of them having the form of the turbinated bone; and in some instances I have seen the discharge like the yolk of an egg. If the secretion is retained for any length of time, decomposition occurs, with fetor, and frequently sanies and ichor, as a result, especially if there is ulceration. The formation, inspissation and obstruction of this secretion, causing it to be expelled with force from the nostril, injuring the vascular texture of the mucous membrane, is one of the principal causes of its inveteracy. The secretion often becomes so copious that it passes down the throat into the stomach while the patient is asleep, causing nausea and vomiting. In dependent positions of the head it sometimes runs from the cavities for a few moments, in a continuous stream. The fetor is often so great as to be observed within a few feet of the person affected, rendering the apartment where the individual is unbearable to others. In persons of a strumous or a syphilitic taint its ravages may extend to the bones, causing caries and necrosis, with discharge of osseous matter, involving parts adjacent to the brain, as once occurred under my own observation, the bones of the palate, nose, and even of the face, dropping out one by one, while the destruction of the soft parts goes on,

until the most hideous, horrible and irremedial deformity ensues; the pain, discharges, and fetor harassing the victim by day and night; rendering him an object of disgust and pity to his friends; life a burthen to himself; loathing his existence, he is almost induced to follow the advice of Job's wife, "curse God and die." It is unnecessary to dwell upon the symptons of this disease, as you are all too well acquainted with them, and they are too obvious to require any extended description. It might be well enough to add, that this rapid and terrible destruction of the parts involved can seldom occur except where there is some systemic taint. Chronic catarrh in a vigorous and healthy constitution, in this latitude, may run on for years and present no other appearance of morbific action than increased secretion, erosions or ulcerations of the mucous membrane. There is one other point, corroborative of the position maintained in this paper, which I desire to refer to, and that is, the prevalence of this disease among the African race, who have emigrated from the southern States to the northern. They may be entirely free from its effects in the south, and yet a residence of a few years in this climate seldom ever fails in producing it among them. In fact, some of the most inveterate cases are seen among this people.

The treatment of chronic nasal catarrh is various as the remedies employed for its alleviation. I wish I could recommend a course of treatment that would insure a cure, something that would act as a specific in restoring the parts to health. It has been said, and well said, "that to cure a disease you must discover the cause, and when it is removed two-thirds of the treatment is accomplished." There is a good deal of truth in this adage, but numbers of cases are treated daily, where the cause is unknown and the remedies contraindicated, who get well through the agency of the *vis medicatrix naturæ*, and in spite of the senselessness of the treatment. The treatment of ozæna, in many instances, demonstrated this last idea very forcibly.

Rhinoscopy, in the last few years, has done much toward elucidating the morbid action in localities hitherto unexplored, and has been a great aid in the proper administration of medicines to the parts affected. It has shown when congestion, erosions, ulcerations and necrosis exist; when hypertrophy and atrophy invaded the tissues; and that condition of the membrane, to which Rokitansky refers, giving rise to polypous outgrowths. But there are parts, even with this adjuvant, it is impossible to explore; hence, in numerous instances, we are unable to arrive at a correct diagnosis of the morbid anatomy of the tissues involved, and must, of necessity, be guided by the symptoms presented.

My experience in the treatment of this disease has been a complete failure, in most instances, so far as producing a cure. Improvement has followed the use of the various remedies, both local and constitutional, recommended by the most reliable authorities on this subject; but I must confess that my success in this latitude has fallen far short of that which they have represented, especially in old and inveterate cases. I deem local remedies of paramount importance. For local applications, one of the best to commence with is a weak solution of permanganate of potash, one grain to the ounce of water. And let me here say, that I prepare the water myself, taking rain water and boiling it, to destroy as much as possible the infusoria always present in this fluid, and then strain. Much of the distilled and medicated waters in the shops is impregnated with this adulteration by long standing, and hence is unfit to be used in this affection. The zinc salts, the sulphate and the chloride, are especially indicated when the discharges are of a thin, dirty yellowish color. In mild cases without erosions or ulcerations, the strength of the various local applications must be increased as the patient can bear them. Do not produce too much pain. Carbolic acid is one of our best remedies to allay fetor, and aids often in restoring the parts to a more healthy action. One important point to remember is, that the membrane must first be cleansed of secretions more particularly from inspissated mucus, so that the medicinal substances may come directly in contact with the diseased surface. One of the best remedies for this purpose is a solution of common salt, half an ounce or one ounce to the quart of water; also a solution of muriate of ammonia is an excellent dissolvent. They can be administered by means of Thudichum's apparatus, or by a large syringe. When there is a thin, gleety discharge, you will find a weak solution of sulphate of copper, one-fourth to half a grain to the ounce of water, a most excellent remedy. It will not do to continue one substance too long at a time. It is best to alternate them every two or three days, unless the improvement appears to be very decided under their use. Change of remedies is beneficial in this disease as well as in most others. We often fail from inattention to this rule. When ulcers or erosions can be seen, I have no doubt, though I have never tried it, the plan of Prof. Allen, making the application by means of an instrument similar to a hypodermic syringe, to the spot,

would be far better than any other method; and for this purpose nitrate of silver is one of the best preparations.

When the maxillary sinus is involved, it will be necessary to extract one of the molar teeth and make an opening into the antrum, through which the injections can be administered. Sometimes the disease extends to the frontal sinus, and these are the most obstinate cases we have to deal with, because it is impossible to make our applications *vias naturales*. The idea has occurred to me, though I have never tried it, that it would be well to dissect the soft parts, by means of a flap, from the frontal sinus, and make a small orifice with a trephine, and administer our local remedies through this opening. I merely suggest it for your consideration. Hypertrophy and atrophy of the nasal membrane are very unfavorable conditions, and, as a general rule, resist treatment a long time; and many cases of this character are never cured. These are the conditions which require strong caustic and ointments. Ointments are more effective here than solutions, because their effects are more permanent. It is often necessary to apply them in full strength, so as to change the diseased action of the part. Boracic acid has been highly recommended in the latter, and the iodine preparations in the former. A weak solution of corrosive sublimate, as an alterative, in hypertrophy, has been used with benefit.

Administration of remedies by the atomizer was at one time used extensively, but experience has not confirmed its utility.

Insufflation through the posterior nares of various powders, is now more fashionable than any other treatment. Of its merits I know scarcely anything. This treatment, however, is worthy of an extensive trial, for it has been recommended to me by a few of our best physicians in the State.

Of course, constitutional remedies are not to be neglected when there is a systemic taint of any kind, and these indications are too obvious to you for me to occupy your time with the treatment.

There is one important point it will be well to impress upon your attention, and that is, the great improvement produced by climacteric influences. A removal to a latitude where the temperature is scarcely ever below the freezing point has benefited and cured, when the disease is not too far advanced, more persons than the most effective remedies. Corroborative of this position, to which allusion has been made, is the fact that the negroes who have emigrated from the far South to a more northern latitude are most universally attacked. I would, therefore, recommend, as a great factor, a removal to such a climate as Florida or Southern California.

CASE OF ACUTE GLAUCOMA IN A CHILD OF EIGHT YEARS, CURED BY SCLEROTOMY, WITH AN ADDITIONAL ACCOUNT OF NINE SCLEROTOMIES PERFORMED FOR GLAUCOMA IN ADULTS.

BY M. LANDESBERG, M.D.,
Of Philadelphia.

The high expectations which were raised by the introduction of eserine into the therapeutics of glaucoma have totally failed. Even the enthusiastic admirers and supporters of this remedy had to yield to the evidence, to which I first drew the attention of the profession, that eserine is not only an unreliable, and in most cases worthless, remedy, in glaucoma, but also a very dangerous one, which, by its primary results, may lull the patient as well as the attending physician into a delusive security, endangering thus the favorable chances of another more efficacious therapeutic action.*

For the present, the only indication in cases of glaucoma must still be *operation*. Until recently, iridectomy was the only operative procedure to which we had to recur for the cure of glaucoma. To this old method, to which the name of Von Graefe is immortally attached, and which had been approved in thousands of cases, a new operative procedure has lately been added. This procedure, called sclerotomy, consists in making an incision at the scleral border of the cornea, as if about to form a flap for linear extraction of cataract without excision of iris, avoiding the prolapse of the latter.

Introduced by Von Wecker, enthusiastically recommended by Mauthner, sclerotomy has been tried by few oculists only. But it has still its future before it. It is not a method of fashion, in vogue to-day, abandoned to-morrow; it is a real enrichment of the therapeutics in one of the most fatal diseases of the human eye. Whether it will succeed to supplant totally iridectomy is an open question; but it always will keep a prominent place in the treatment of glaucoma. It is a simplification of the operative procedure; it has many advantages over iridectomy, and shares with the latter its curative effects.

In my article "On the Use of Sclerotomy in

* See my article on the "Therapeutic Use of Eserine in Glaucoma," *Knapp's Archives of Ophthalmology*, Vol. VIII, No. ?.

Glaucoma," just issued in Von Graefe's *Archives of Ophthalmology*, Vol. XXVI, No. 2, I give a full account of thirty-five sclerotomies, performed in the years 1876 to 1879, in the different forms of glaucoma. The results which I have obtained by this new procedure justify me in setting forth the following instances in which iridectomy has to be abandoned and replaced by sclerotomy. These instances are:—

1. Absolute glaucoma.

2. Secondary glaucoma, and glaucoma like conditions of the eye, as observed in iritis, serous choroiditis, in certain forms of keratitis, etc.

3. Cases of glaucoma in which iridectomy had been made, and the reappearance of the glaucomatous process indicates the repetition of the operative procedure.

In all other instances it entirely depends upon the personal feelings of the surgeon, whether in his proceedings he prefers to be backed by high authorities, or by his own judgment only. That sclerotomy is apt to bring about a full effect in all other forms of glaucoma has been illustrated by my first communication, and will receive further evidence from the following cases, which I have observed during the last year.

CASE 1.—C. B., workman's son, eight years old, had been suffering through all the summer, from intermittent inflammations in both eyes. In the first days of November, after a period of relative rest, intense symptoms of inflammation set in, in the right eye, the sight of which rapidly decreased. Examination, made November 10th, showed, left eye, some small infiltrations around the corneal border; right eye, multiple infiltrations of the cornea. Pronounced picture of subacute glaucoma. Aqueous humor dim; intraocular pressure intensly increased; pupil medium dilated; optic disc deeply excavated; intense venous hyperæmia of the retina. Vision reduced to counting fingers at 5′.

Instillations of eserine acted at first very favorably. Aqueous humor cleared up; tension decreased and pupil contracted somewhat. But from November 13th the morbid process exacerbated, evolving, on November 16th, into acute glaucoma. Vision was reduced to quantitative perception of light. Background of the eye could not be seen.

November 17th, I performed downward sclerotomy. Course of operation and of healing was normal. Tension decreased immediately after the operation. All symptoms of inflammation and irritation subsided very rapidly. On the second day tension was normal, anterior chamber clear and perfectly restored.

The final examination, November 24th, showed irritation vanished; pupil of normal shape and reaction; optic disc somewhat hyperæmic, but no trace of excavation; some retinal ecchymoses in the state of resorption. Vision (reduced on account of the existing maculæ corneæ) = $\frac{15}{40}$, Jæger 3. Field of vision normal.

CASE 2.—C. F., Farmer's wife, 49 years old, came under my notice June 19th, with acute glaucoma of the left eye. She was not prepared at the time for operation, but something had to be done in order to alleviate the severe neuralgic pain. In this emergency I resorted to paracentesis corneæ, repeating twice the escape of the aqueous humor. The relief was immediate, and there was considerable decrease of tension. When I saw the patient, twenty-four hours afterward, I was not a little astonished at the improvement of the eye. Symptoms of irritation were but slight, intraocular pressure was almost normal and pupil but very little dilated. Background of the eye showed slight excavation of the optic disc and venous hyperæmia. V = $\frac{15}{70}$. Field of vision intact. Improvement progressed in the following days, bringing complete recovery.

When, after eleven weeks of perfect health, acute glaucoma reappeared, I performed, September 19th, downward sclerotomy, with the most favorable result. Intraocular pressure diminished instantly. The course of healing was very short; the restitution complete. Tension and pupil became normal and V = $\frac{15}{30}$. Field of vision was free.

CASE 3.—O., grocer's wife, 59 years old, had iridectomy performed on her for acute glaucoma of the left eye, about two months previous to her coming into my notice. The operation afforded but temporary relief. Glaucomatous attacks set in again, with greater violence than ever before.

Examination, made September 15th, showed, left eye, media cloudy, anterior chamber shallow. Broad upward iridectomy. Eyeball of stony hardness. Fundus oculi cannot be seen. Vision reduced to counting fingers at 5′. Very intense symptoms of irritation

September 16th I performed upward sclerotomy. Course of operation was normal. Tension decreased but slightly after the operation. The healing process was interrupted by frequent acute exacerbations. After a long and tedious period of convalescence, the final result, October 29th, was: media clear; anterior chamber almost normal. Intraocular pressure only slightly above normal condition. Somewhat deep excavation of the optic disc. V = $\frac{15}{70}$, with + 6 Jæg. 3. Field of vision limited in the upward-inward quadrant.

Case 4.—F. G., shoemaker, 39 years old, had been suffering from intermittent inflammations of his right eye, from July 4th, when it was struck by a fire cracker. At first the paroxysms were short and subsided without impairing vision. In the last month the symptoms of inflammation remained stationary, and there was a gradual loss of sight.

Examination, December 15th, showed, right eye, deep ulceration on the lower third of the cornea, with diffuse infiltration; anterior chamber somewhat cloudy; pupil medium dilated; immovable intraocular pressure = T. 2; deep excavation of the optic disc; spontaneous arterial pulsation; vision reduced to counting fingers at 8′.

The administration of eserine brought complete contraction of the pupil, but no improvement whatever of the morbid process. December 20th, I performed downward sclerotomy. During the section small prolapse of iris occurred, the reposition of which succeeded. Tension decreased immediately, and the morbid symptoms subsided very rapidly; recovery was complete. Pupil and tension became perfectly normal and V = $\frac{15}{30}$. There was no excavation of the optic disc and no limitation of the field of vision.

Case 5.—D. C., weaver, 57 years old, applied to me February 4th, with subacute glaucoma of his left eye; pupil was medium dilated; intraocular pressure = T. 1; optic disc deeply excavated, with atrophic ring; spontaneous arterial pulsation. In the peripheric part of the retina there were some choroidal atrophies and pigment macerations. V = $\frac{20}{70}$, with + 6 Jæg. 5. Field of vision limited in the lower inner quadrant.

February 6th. Sclerotomy downward. Small prolapse of iris occurred after the section had been made, the reposition of which succeeded perfectly. Slight decrease of tension after the operation; healing process very favorable. Final result, V = $\frac{20}{30}$, with + 12 Jæg. 1. Field of vision much enlarged; pupil roundish; dilated but slightly above the normal condition, of fair reaction; intraocular pressure normal; excavation of the optic disc flatter.

Case 6.—G., peddler's wife, 56 years old, came under my treatment April 10th, with subacute glaucoma of the right eye. Anterior chamber was very shallow; pupil irregular, very sluggish, medium dilated; intraocular pressure about T. 1; deep excavation of the optic disc, with arterial pulsation. V = $\frac{20}{40}$ Jæg. 3, with + 10. Field of vision limited in the upper half, almost to the point of fixation.

April 11th, downward sclerotomy. Course of operation and of healing process normal. After the operation the intraocular pressure is below normal condition; it increases pathologically in the following day, and becomes normal on the third day; final result, V = $\frac{20}{40}$ with + 10 Jæg. 2. Field of vision considerably enlarged; pupil round, of almost normal reaction; no arterial pulsation; no change in the optic disc.

Cases 7, 8.—W. O., farmer, fifty-five years old, applied to me June 30th, in the following condition: Right eye, subacute glaucoma; pupil medium dilated, of slow reaction; tension = T. 1; optic disc slightly excavated, with atrophic ring; venous hyperæmia. V = $\frac{15}{70}$ with + 10 Jæg. 4. Field of vision limited downward and inward, in the latter instance almost up to the point of fixation. Left eye, chronic inflammatory glaucoma; ciliary veins greatly enlarged; cornea hazy, of diminished sensibility; anterior chamber somewhat shallow; pupil medium dilated, immovable; tension moderately increased; opacities of vitreous. Fundus oculi only indistinct. Vision counting fingers at 5′.

July 2d, downward sclerotomy in both eyes. In the right eye prolapse of iris during section, the reposition of which did not succeed. Iridectomy was made. In the left eye sclerotomy was successful; tension became normal; cornea cleared up; pupil and vitreous remained unchanged; vision improved to counting fingers at 15′; optic disc showed deep excavation and considerable hyperæmia. In the peripheric retinal parts there were choroidal atrophies and particles of pigment.

Case 9.—R., shoemaker's wife, forty-nine years old, came under my treatment with glaucoma simplex of both eyes. Iridectomy, performed June 21st, checked the morbid process and improved vision. While the condition of the right eye remained stationary, the left eye showed, from the first days of August, renewed increase of tension, with failing of the sight and narrowing of the field of vision. Sclerotomy, successfully performed, August 15th, had the most favorable result. Tension became normal; vision increased from $\frac{15}{100}$ to $\frac{15}{30}$, and field of vision enlarged.

Case 10.—C., peddler, sixty-seven years old, applied to me October 3d, in the following condition: Right eye, iridectomy upward; tension normal. V = $\frac{20}{70}$. Field of vision limited in the upper inner quadrant; slight excavation of the optic disc, with atrophic ring. Left eye, eyeball of stony hardness, intense sub-conjunctival and conjunctival injection; cornea opaque, with calcareous concrements; anterior chamber cloudy;

pupil ad maximum dilated; secondary catarrh; intense neuralgic pains. Iridectomy of the right eye had been made, for glaucoma, in Germany, in the year 1876. At this time the left eye had been blind for two years, without causing any annoyance to the patient. The latter set in in January, 1880.

October 4th. Downward sclerotomy. Course of operation normal. Healing process very slow and interrupted by frequent exacerbations. Final result favorable. All symptoms of irritation vanished and tension decreased very considerably.

General Remarks.—These cases show most evidently the high therapeutic value of the new operative procedure. In the nine cases in which sclerotomy was successfully performed, the latter succeeded to check the glaucomatous process, to reduce the morbid increase of the intraocular pressure and to improve vision. In these instances sclerotomy had the same beneficial effect as of a successful iridectomy, and had besides this great superiority over the latter, that, by leaving the iris intact it saved the eye from so many optical disadvantages (symptoms of dazzling, polyopia, etc.) which are often caused by the coloboma.

The first case which heads my present communication is highly interesting from many a point. Acute glaucoma is a very rare occurrence in children; it is the only one that I observed among 13,000 patients. The fine result obtained here by sclerotomy may be regarded as the best exemplification of the value of the new procedure. Before its introduction into the therapeutics of glaucoma, we had had only one recourse, in iridectomy. A permanent mutilation of the eye would have been the inevitable consequence; whereas sclerotomy restored the eye to its normal condition. The same favorable results have been obtained in Cases 2, 4, 5, 6, and 8. In Cases 3 and 9, in which glaucomatous process recurred after a successful iridectomy, sclerotomy made superfluous a repeated excision of iris, and checked the morbid process. In Case 10 sclerotomy gave abundant proof that in this instance it is the best substitute for iridectomy. In Case 7 the intention of the operation failed; prolapse of iris occurred, and iridectomy had to be made. It shows that we do not in the least endanger the condition of the eye by first trying sclerotomy; being enabled, in any emergency, to add to the section of the sclera the excision of a piece of iris, and thus change sclerotomy for iridectomy.

Hospital Reports.

DROPSY IN CARDIAC DISEASE.

A Clinical Lecture delivered at the Hospital of the University of Pennsylvania, Sept. 27, 1879.

BY WILLIAM PEPPER, M.D.,
Prof. of Clinical Medicine in the University of Pennsylvania.

REPORTED BY WM. H. MORRISON, M.D.

Gentlemen—I have to-day two patients who come together very well as illustrating the different significance of the same symptom arising from different causes. This is particularly true in dropsy of the legs arising from cardiac disease.

This young man was admitted a few days ago. His history is as follows. He is twenty-two years old and a blacksmith by trade, but lately has been a bartender, and has taken more liquor than was good for him. He considered himself perfectly well, until three or four weeks ago, when he noticed pain in the chest, shortness of breath, decrease in the quantity of urine, inability to lie down, and afterwards dropsy of the legs. I do not think that his disease came upon him as an acute attack a few weeks ago.

I shall, in the first place, examine the heart. The heart is enlarged. Its action is very rapid, weak and irregular, and on auscultation I find murmurs. One of which, at least, is organic, that is, one resulting from insufficiency of the mitral valve. This is so harsh and strong, and transmitted so far downward and to the left, that there is no doubt but that it is organic. I cannot believe that the disease developed so rapidly as our patient thinks. It is probably a case where there has been a latent cardiac disease for some time, which has been aggravated by an acute attack. There is a great deal of congestion of the liver, and some congestion of the lungs. There is a high degree of dropsy of the legs. It is rather remarkable that the swelling of the feet is not nearly as great as that of the calf of the leg. This seems to be due to the hardness and tightness of the skin of the feet.

When we meet with a case like this, where we have a cardiac murmur and œdema of the legs, it is, of all things, important that we should learn the exact cause of the dropsy. The gravity of this œdema will depend entirely upon the cause that produces it.

Let me now call attention to this lady, who is fifty-nine years of age and has had swelling of the feet and ankles off and on for the past four or five years.

Here we find, upon examination, that the heart is exceedingly weak, feeble and frequent. We have here a marked *arcus senilis*, due to fatty degeneration of the corneæ. There is no valvular murmur, but there is evidently fatty degeneration of the heart.

In some cases this œdema of the feet is evidently connected with anæmia, a watery condition of the blood. The œdema in these cases is to be removed by the remedies useful in anæmia. There are other cases of cardiac disease, where the swelling of the legs is connected with a state of plethora. In other cases there is some ob-

structive disease of the heart, and great obstruction to the passage of the blood from the heart. This leads to venous congestion and effusion.

We meet with other cases connected with heart disease, due to the failure of the power of the heart to propel the blood through the whole circulation. Lastly, we meet with œdema in cardiac disease, where the kidneys become involved, and it is in this last condition that œdema becomes most marked.

In this lady we have had transient œdema coming on during the day and disappearing at night, no evidence of disease of the kidney, no organic disease of the heart, so that we must attribute this œdema to debility of the circulation.

In this young man we have a serious combination, because we find that the urine contains a large amount of albumen. In this case we have existing obstructive disease of the heart and a renal complication. This is a very common combination, and wherever you have swelling of the feet in cardiac disease, you should examine the urine carefully. We have not yet arrived at a clear understanding of this case. If we find only albumen in the urine, it will be probable that there is only congestion of the kidney, which will disappear when the congestion is relieved. We may find tube casts, showing that there is also organic disease of the kidney. Before meeting you again I shall have a microscopic examination of the urine made, and when we meet I shall take up the case at this point.

September 30th. Gentlemen, I again bring this young man before you, in order that we may study his case more carefully. Further examination of the urine has shown that there is no organic kidney trouble. There was, on Saturday, as you will remember, a considerable amount of albumen in the urine, the feet were œdematous and the dropsy extended some distance up the leg. We also found cardiac disease, and I told you that this case illustrated the relations between one kind of dropsy and cardiac disease, in that we had, with evident obstruction of the venous circulation, congestion of the kidney. This patient's expression when he came into the hospital indicated an intense degree of anæmia.

On Saturday I first asked you to observe the different relations that dropsy bore to cardiac disease. How, in some cases, it was due simply to weakness of the heart, debility of the cardiac walls, so that the heart was unable to propel the blood around the whole current of the circulation, and congestions were produced at the most dependent parts, and œdema became established; secondly, that patients with cardiac disease sometimes suffered from such impairment of nutrition that they became intensely anæmic, and, as in all cases where we have a watery condition of the blood, there is a great liability to the escape of serum and the formation of dropsies; thirdly, in cases in which there is marked obstruction or marked regurgitation at some orifice of the heart, we find that the venous system becomes engorged and dropsy ensues; and, lastly, in some cases of cardiac disease we find special congestions of various organs, the lungs, liver or kidneys, and when in connection with cardiac disease there is renal congestion, we are pretty apt to have dropsy, and especially apt to have œdema of the feet. So that, when you meet with a patient who has dropsy of the feet, the first questions to be settled are: What organ is at fault? Is there any organic disease? Is it the liver? In hepatic dropsy we have ascites developed. Secondly, are the kidneys at fault? Is the heart also at fault? Having found out, in any case of œdema, what organ or organs are at fault, we must next discover the special causes that exist.

I find in this man intense renal congestion and marked œdema, but no indication of inflammation of the kidney. Let us now study the condition of the circulation in the heart, liver, and kidneys. The apex beat is nearly in its natural position. When I place my hand over it there is a very unnatural feeling imparted to it. In the first place the impulse extends over a larger area than natural. The natural impulse extends over an area about the size of a silver half dollar. In the second place, there is a distinct thrill imparted to the hand, which is very marked and is felt with every impulse. On percussion I find that the cardiac dullness does not much exceed the normal. When I auscult the heart, there is a strong murmur heard at the base. One murmur and then one healthy sound. It becomes louder as I descend and go to the left. It attends the contraction of the ventricles—it is a systolic murmur. It is heard very powerfully around the left side of the chest. It is transmitted in the axis of the heart and in the direction that the blood takes in coming through the mitral valve. This is, therefore, disease of the mitral valve. The murmur attends the contraction of the ventricles when the mitral valves should be closed; therefore the mitral valves are insufficient and the murmur is a regurgitant murmur. Is there, also, any regurgitation through the tricuspid valve? The murmur is heard to the right of the heart, but it is lost too quickly. While we find that the jugular veins are filled with blood, they pulsate very little if at all. If there was insufficiency of the tricuspid valve the blood would be driven back into the right auricle and thence into the jugular veins, causing marked pulsation in the neck. Since the murmur is not transmitted much to the right, and there is no pulsation of the jugular vein, we may consider that, practically, there is no disease of the tricuspid valves.

The heart has, singularly, not become much enlarged, which makes me think that this is rather an acute case. If this had been an old trouble, and six weeks ago an acute affection had increased the trouble, we should find the heart enlarged. So that the absence of enlargement inclines me to believe that this is the result of an acute endocarditis. The aorta does not get as much blood as it ought. The consequence is that the patient is excessively pale, because, probably, half of the blood is forced back into the left auricle. This blood meets the blood returning from the lungs by the pulmonary veins, and, owing to the power of the left ventricle, it greatly impedes the passage of blood, and almost alters the direction of the current. In consequence of this, the passage of the blood through the lung is greatly impeded. Therefore it was that there was such intense congestion of the

lungs, shown by the moist and crackling râles heard over the base of both lungs. We still hear a good many râles over the base of the lungs, chiefly on the left side. The vessels, in this case, seem to be very strong and elastic, allowing such marked congestion. If they had not been so strong they might have given way, causing pulmonary apoplexy or hæmoptysis. Here we merely have congestion and some escape of serum. But, notwithstanding this, the congestion has done its full work. The right side of the heart has not been able to propel the blood through the lung, and thus we find that the right side of the heart has been greatly congested. The veins have not been able to empty the blood into the heart, as we see by looking at the jugular veins, and we find that the ascending cava, which carries the blood not only from the lower extremities but also from the hepatic and portal circulations, is also congested. In consequence of this, we find dropsy of the lower extremities and remarkable congestion of the liver. The epigastric and hypochondriac regions are much enlarged. When the man holds his breath you can see a pulsation in the epigastrium, and when the hand is placed over this region a distinct impulse is felt. When we examine the liver by percussion, we find that it extends from the fifth interspace downward, for a hand's breadth below the normal line. We have here an enlargement of at least 25 or 30 per cent. The edge of the liver can be felt at the point indicated on percussion. In this great congestion of the liver we find another proof of the strength and elasticity of the vessels in this young man. When the veins are so engorged, the watery portions of the blood usually exude into the peritoneal cavity, causing ascites. In this case there is, at present, no trace of ascites.

Here, then, we see what important results may follow this lesion of the mitral valves—congestion of the lungs, liver and kidneys, congestion of the right side of the heart, of the ascending and descending cavæ, congestion of the veins of the lower extremities and œdema. The œdema is owing, in part, to the great extent of the venous stasis; but this is not the only cause. We find a further cause in the special congestion of the kidneys, as shown by the extreme albuminuria. When the kidneys are thus congested, they are not able to perform their function properly, and some of the effete matter remains in the blood. This poisoned blood will not be transmitted as freely by the capillaries as will healthy blood, and congestion of the veins and œdema results. I would add that, probably owing to the small amount of blood passed into the general system, all the functions have been poorly performed, especially the digestion. Owing to this the patient's blood was very watery, and he was exceedingly anæmic. So that, in a case of this kind, we have several indications to meet in promoting the removal of the dropsy.

In regard to this pulsation in the pit of the stomach, you will often observe it in cases of this kind. The pulsation is sometimes so marked that it gives rise to the idea that the liver itself is pulsating. This sometimes occurs, but the pulsation is usually due to the transmission of the impulse from the heart itself. In this case I am satisfied that it is a transmitted impulse from the heart, which lies right on top of the liver, separated only by the diaphragm.

Now let us see what we should do for a patient in this condition. There are some cases in which we have nothing to do but stimulate the action of the heart. Take, for instance, such a case as I saw a few days ago in private practice. A man who has been overworked has a slight regurgitant mitral murmur which had never caused any trouble. He begins to lose general strength, is easily tired, the pulse becomes more frequent and feeble, face is pale, he has to stop and pant for breath on going up stairs, and his feet begin to swell, but there is no albumen in the urine. There is a little congestion of the lung, the surface is cool and the pulse is irregular, intermittent, frequent, very weak and small. Now, there is a case of œdema of the lower extremities, due solely to cardiac failure. You will find in such cases that absolute rest, small quantities of food at short intervals (because the digestion is weak), a little alcohol and plenty of digitalis, will in a few days cause the dropsy to disappear.

Now one of the elements in the treatment is, as I have said, absolute rest. You will find that the simple fact of making such a man sleep upon the ground floor will do more for his comfort than any drugs. It prevents him from having to lift the weight of his body in going up stairs, and also enables him to take exercise in the open air without going up or down stairs. The carrying out of this single element in the treatment of heart failure will often be followed by a disappearance of the dropsy, which seems almost miraculous.

Again, I spoke of the use of food in cardiac disease with dropsy. It might be said that in all such cases a diet of liquid should be preferred to a solid diet, for the reason that a liquid diet stimulates the action of the skin. This is true whether you give strong meat broths, beef tea, or milk; for after all beef tea is nothing but a mineral water containing various salts and a little albumen in solution. In the same way milk contains a great many salts and with these some albumen and sugar. Therefore a liquid diet of milk and broths is really a diuretic and diaphoretic in itself, while we also present the elements of nutrition in an acceptable form. I think I may say that in almost every case of cardiac disease with dropsy, a diet chiefly liquid is an important element in the treatment. This becomes more important when the digestion is weak or in any way deranged. In cases with hepatic and renal derangements I think it may be laid down as the rule, that a liquid diet is to be used. In case of hepatic involvement, in which there is a diminished secretion of bile, you will find that skim milk, or better, buttermilk, is very useful, because they contain no fat. The food should be taken at short intervals and in small quantities. A small quantity of green vegetables and lean meat will often have to be allowed, in order to satisfy the patient.

I spoke of alcohol, and this is a very important element in the treatment. The strong forms of alcohol are injurious, but the weaker forms, as diluted sherry or gin diluted with water, which, on account of its containing juniper berry, is diuretic, are

well digested and stimulate the action of the heart. Lastly, digitalis, which in this condition is the most valuable of all drugs, may be given freely, watching its effect. Twelve drops of the tincture may be considered an average dose.

In cases where we find that instead of there being failure of the heart, the heart is acting powerfully, and there is extreme nervous congestion, we have to alter our treatment. Here, while we use the same elements—rest and the modified diet—alcohol will be injurious and digitalis will not of itself suffice. We have now to take away this condition of congestion. We have to relieve the heart, lungs, liver and kidneys, by depletion of the engorged veins. For the relief of the lungs we apply dry cups over the lungs and administer saline expectorants. In the case of the liver, repeated doses of mercurials, followed by a saline laxative, should be used. In no condition of the system will you see better results from repeated doses of mercurials followed by a saline laxative, than in hepatic congestion from cardiac disease. Three grains of blue mass once or twice a week, followed by a saline, will be a most important and valuable element in the treatment. In the case of the kidneys, dry cupping and saline diuretics should be used. Buttermilk is also useful in this condition.

In our patient it is the last form of treatment that we need. Twice a week a pill of blue mass, and during the interval cream of tartar water taken freely, moderate doses of digitalis and a restricted liquid diet, constitute the treatment.

There is another question to be considered, that is, the treatment of the anæmia. Some practitioners fall into a stereotyped way of treating cardiac diseases. Some give only iron, others give only digitalis; but the only right way is to treat the disease according to the indications of each case.

Iron is useful where there is anæmia. It does not make much difference what form of iron is used, but preferably the diuretic salts, the potassii et ferri tartras, the citrates and the chlorides, should be used in cardiac dropsies. It should be given in large doses, beginning with a moderate dose and slowly increasing it. In the present case the patient has been taking the tincture of the chloride of iron, the effects of which have been shown by the improvement of color and digestion and the lessening of the dropsy. We have now spoken of the elements of heart failure, venous stasis and anæmia, as entering into the treatment of heart affections.

We will find that if our diagnosis in this case is correct, and there is no organic disease of the kidney present, and the albumen is simply the evidence of congestion, as we improve the tone of the heart, and restore the nutrition, the albumen will disappear from the urine. We will watch the case with interest, to see if this will be the course.

He is taking ten drops of the tincture of iron, with twenty drops of the tincture of digitalis. He will have dry cupping over the kidneys and liver, and blue mass twice a week, followed by a laxative.

The remarks that I have made to you indicate the rational treatment of cardiac dropsy. I have little doubt but that in the course of six or eight weeks this treatment will restore our patient to almost perfect health, but he will need to exercise the greatest caution.

The extent to which organic disease will diminish, if you can keep the heart perfectly quiet and have no tax or overwork placed upon it, is wonderful. Even in a patient as old as ours, I have seen organic murmurs actually disappear after two or three years. This result, which is rare in the adult, is quite common in children. So much so that if you can only induce the parents of a child with organic heart disease to follow out a proper hygienic and medicinal course of treatment, you will find, after several years, in a notable proportion of the cases, that the child not only remains well, but that from year to year, as you watch the case, the organic disease itself becomes modified, that the valves are being restored to their normal form, and that the signs of organic disease are slowly passing away.

I have watched cases of this kind, and after the child has reached adult life, I have been unable to find any signs of heart disease, and watching the case on through life there has been no development of cardiac disease.

When this man has recovered from his acute condition, I shall give him one or two grains of potassium with $\frac{1}{60}$ of a grain of corrosive sublimate. This will be stopped at intervals, so as not to derange the digestion. With this we shall combine rigid hygienic treatment, and we may hope to relieve, to some extent, the cardiac trouble.

Periscope.

The Value of Colotomy.

This operation is strongly recommended by Mr. Christopher Heath, F.R.C.S., in the *British Medical Journal*, January 1. He says:—

I do not, of course, mean that colotomy is desirable in every case of cancer, for the progress of some cases is slow, and much may be done to relieve pain and promote comfort by the use of morphia suppositories, or of starch and opium enemata, and the careful selection of bland and unirritating food and drink.

As regards the operation itself, I would say that, though it often is extremely easy and simple, yet, in some cases, it is of the greatest difficulty. In a case of obstructive disease, the colon is often distended and easy to reach; but, again, when distention is great, the colon may be contracted, and the small intestines overlap it completely, and cause great difficulty; or the peritoneum, distended with air, may closely simulate the bowel. Again, the anatomical arrange-

ment of the meso colon may be such as to render it impossible to reach the bowel without opening the peritoneum. Should the peritoneum be opened, I believe the best mode of proceeding is to bring up the colon to the opening, and stitch it carefully before opening the bowel—so that the two peritoneal surfaces may be well in contact and rapidly adhere, when a good result may be anticipated. It is said, by a distinguished lithotomist of the day, that every case of lithotomy has its own peculiarities; and the same may, I think, fairly be said of colotomy. Although my experience of the operation is now not inconsiderable, I must confess to a feeling of relief when I have fairly opened the colon without misadventure.

In the after-treatment of cases of colotomy, some little care is required in washing out, periodically, the diseased piece of bowel below the artificial anus, for, if this be neglected, the mucous secretion collects, and is apt to irritate. It is undoubtedly the fact, though it is difficult to explain it, that fecal matter does occasionally find its way into the rectum, in some cases; but the bulk of the fæces is, of course, discharged at the loin, and with great regularity, and singularly little discomfort. A simple bandage, with a pad of tow or wool, applied over the anus, is sufficient to prevent injurious friction of the part; but if, as sometimes happens, there be a tendency to prolapse of the mucous membrane, another air-pad may be added.

On Excision of Cancer of the Rectum.

An analysis of 140 cases of excision of cancer of the rectum is given by Dr. A. Kelsey, in the New York *Medical Journal* for Dec. last. From their study he draws the following conclusions:—

1. The fatal results which have thus far been recorded as following this operation nearly all occurred in cases where, from the extent of the disease, such a result was not improbable.

2. When the disease reaches above three inches, or involves neighboring parts to such an extent as to render its entire removal without injury to the peritoneum questionable, the operation is contra-indicated.

3. Although there have been a few cases of cure, such a result is so rare as not to justify the exposure of the patient to the risk of immediate death which attends the attempt to remove extensive cancerous disease.

4. The operation is chiefly valuable as a palliative measure, and as such it is applicable to cases where the disease has not made extensive progress.

5. As a palliative measure in proper cases, it compares favorably with the results of lumbar colotomy, both in prolonging life and in relieving pain.

6. The operation is not followed by an annoying incontinence of fæces, except in a small proportion of cases.

7. The operation is not a substitute for lumbar colotomy in cases where the disease has reached more than three inches from the anus.

8. There is no proof that the operative interference shortens life by hastening the progress of the disease.

Extraction of Foreign Bodies from the Ear.

At a recent meeting of the Surgical Society of Paris, M. Verneuil stated that when a child having a foreign body in the ear is brought to the hospital before any attempt at extraction has been made, there is rarely any difficulty in removing the foreign body. If, however, such attempts have been made, chloroform should be employed. If the tissues have been irritated, if the membrana tympani has been torn, the application of an instrument, however gently, causes more or less severe pain and provokes movements so violent that the auditory organs are in danger of being seriously injured. Chloroform has this great advantage, that by rendering the patient insensible to pain, it prevents violent motion. M. Verneuil stated that he has seen children brought to the hospital by physicians in attendance on them who were firmly convinced of the presence of a foreign body in the meatus externus, and who, under this conviction, had introduced instruments and made attempts at extraction, with the effect of lacerating the tissues, tearing the membrana tympani, and even laying bare the petrous bone, adducing as proof of the presence of a foreign body the sound given by the instrument on striking the bone thus uncovered. M. Verneuil succeeded with difficulty in convincing them of their error. Having administered chloroform to the unfortunate child he then demonstrated that the body sought for existed only in imagination, and that the only reality was the injury to the child. According to M. Verneuil the methods of treatment should be employed in the following order: First, injections of water, suitably practiced; secondly, if the foreign body resists, chloroform to be administered without hesitation, as instruments may then be employed without danger to the patient, as, for instance, a forceps or scoop to seize or draw out the foreign body.

The Diagnosis of Rheumatic Gout.

Mr. Jonathan Hutchinson says, in an article in the London *Medical Times and Gazette*:—

Of the peculiarities presented by joints which have suffered from rheumatic gout, two stand out before all others in their value as means of diagnosis. I allude to the dry grating caused by the removal of cartilage, and the development of lips. We may venture to assign the chief place to the second of these, for it is the one which is earliest to be found. Grating is never present excepting at an advanced stage, and although very characteristic then, its value becomes, of course, much limited by that fact. Nodosities and lips, on the contrary, are among the very earliest of the products of this malady, and are often, indeed, present before the patient is aware that he has had any inflammation in the joint concerned. Nor have we, so far as I know, any reason to think that they occur to any characteristic extent in association with any other causes. On the contrary, I believe that their diagnostic value is as great in rheumatic gout as is that of chalk concretions in true gout. Our differential definition of rheumatic gout may then, I think, be based on these peculiarities, and we may say that any form of joint disease which tends to the pro-

duction of lip-like outgrowths at the margins of the cartilages has a claim to be placed in this category. I have already hinted that there are many varieties, some of them probably of considerable clinical importance, which are grouped under this head, and that in a certain large group, occurring in patients under middle age, while removal of cartilage is common, outgrowths of bone are rare, and if present usually small.

For the last few years I have been in the habit of using these outgrowths for the purpose of diagnosis, in a somewhat novel way. I had often been struck by the marked prominence of these rheumatic lips on the condyles of the femur in museum specimens, and it occurred to me that they ought to be perceptible during life. I examined the knees of a few patients who had the disease in an advanced stage, and found that I could detect them very easily. Afterwards, with some practice, I found that I could appreciate their presence even in comparatively early stages, and also that they are frequently present when the patient has no external deformity whatever. By degrees, and after the examination and comparison of a great number of patients, I have come to rely with much confidence on this symptom. If you wish to employ it successfully you must first practice carefully on healthy joints. In many, if not in most, there is a ridge at the part referred to, more or less resembling the pathological lip. The distinction between health and disease can only be acquired by practice. In examining a knee I prefer to place myself in front of my patient, and to employ both hands at once. I place the finger-tips of one hand flatly over the edges of the one condyle, and those of the other on the opposite, and then direct him to bend and extend the joint slowly several times in succession. In this way you may find the edges and appreciate their elevation without risk of error. I much prefer to use the fingers flatly at first, and not to employ their tips, as I think there is less risk of error in estimating elevation; but afterwards I use the tips in order to determine whether the lip overhangs. In well-marked cases it curls outwards.

These condyloid crests, as I have already observed, are not to be expected in all cases. As a general rule they are present only in those who have passed middle life. You must not expect to find them in the young. In the latter, absorption of cartilage without osseous outgrowth is the rule. In the aged however, these crests are invaluable as symptoms. I have very often recognized them in cases in which the patients were not aware that the knees had ever suffered. I have often been able by their aid to say which knee had suffered most frequently, and have found the patient's statement confirm my inference The symptom is of especial use in those cases in which we are consulted, not on account of joint affections, but for iritis, or lumbago, or a skin disease which we suspect to be of arthritic origin.

Prognosis of Cerebral Hemorrhage.

M. Jorisenne has published an interesting memoir on this subject. in the *Annales de la Soc. Med. Chirurg. de Liège* :—

The prognosis for the first few hours after the attack should be guarded; according to Rosenthal the diminution of intra cerebral pressure and the regularization of the circulation is marked by the return of consciousness and speech. the respiration and action of the heart remaining calm, deglutition, motility and tactile sensibility becoming re-established at the same time that a rise of temperature occurs. On the contrary the immediate prognosis is bad when there is persistent coma, lasting thirty-six or forty-eight hours, with complete loss of reflex irritability, irregular and snoring respiration, small pulse with intermissions in its beat, paralysis of the sphincters with dilatation of the pupils, which were primarily contracted. A sudden fall of the temperature to 35°–35.4° C., persisting for several hours after the apoplectic attack, is one of the signs of a fatal termination (Bourneville); a great elevation of temperature (to 41°–42.5° C.) is also of bad augury.

Convulsions and contractures occurring at this early stage indicate that effusion has taken place into the meninges or ventricles, and recovery after such lesions is very exceptional. M. Jorisenne, in his memoir, devotes more attention to the prognosis after the first few days have passed without fatal result.

Persistent cephalalgia is generally unfavorable, as it indicates a cortical or cerebellar lesion.

Intellectual derangement, when it persists several weeks, generally passes into imbecility, or into weeping dementia (Brouardel).

Aphasia, rare in cerebral hemorrhage, but more frequent in softening, persists long after amelioration is observed for the paralysis; if, after a few weeks, it passes into paraphasia, speech will probably be reëstablished; by paraphasia is understood the substitution of one word for another, the patient in favorable cases being conscious of his errors.

Verbal amnesia is of more favorable augury than aphasia; the patient has forgotten the words but can repeat them after another person, and may be thus taught his letters, etc., as a child. Hemiplegia is a grave and common symptom; cross hemiplegia is of more serious import, and if there are facial troubles is a sign of meningeal hemorrhage at the base.

If, in conjunction with cross hemiplegia (hemiplegie alterne) there are pains at the occiput, troubles of hearing, of deglutition, and of respiration, death is imminent. When, after a variable period, contractures appear in the paralyzed limbs, the paralysis will, thereafter, remain permanent.

Anæsthesia persists rarely after the ictus; when it supervenes later it proves permanent. Deafness is grave, for it indicates that the lesion is situated at the base. Conjugated deviation of the eyes with rotation of the head toward the paralyzed side announces a rapidly fatal termination (Desnos); rotation of the head toward the non-paralyzed side is transitory. Visual troubles are rarely of long duration: atrophy of the optic nerve is limited and the hemorrhage must be very abundant to induce sufficient compression of the cavernous sinus to bring on hydropthalmia or sanguinolent effusion into the retina.

Cerebral atrophy, eschars, and pulmonary le-

sions are frequent consequences of cerebral hemorrhage.

Lung troubles kill the great majority of those who survive the attack (Charcot, Brouardel). Repetition of the attack is the rule in cerebral hemorrhage; the lesions are ordinarily multiple and each attack aggravates the situation.

According to Durand-Fardel, death is common when the attack supervenes in subjects from sixty-five to seventy years of age; recovery more frequent from forty to fifty.

The Induction of Abortion as a Therapeutic Measure.

At a late meeting of the Obstetrical Society of London, Dr. Priestly read a paper on this subject. He considered that the indications for the induction of abortion, as distinct from the induction of premature labor, had never been laid down with sufficient precision in this country. It was usual to say that each case must be judged on its merits, and this lack of rules might unfortunately lead to serious abuse. Examples had repeatedly come within his knowledge, where abortion had been provoked for reasons which seemed to him quite inadequate. Though the medical man was no doubt acting in entire good faith in these cases, it would have been very difficult to sustain his action in a court of law. For instance, in one case abortion was induced at the fourth or fifth month, on account of a bad rupture of the perineum at the last confinement. In a succeeding pregnancy a sound was introduced with a similar object at the end of a month; this, however, had no effect, and she went to full term, and had an easy and natural labor. In a second instance an attempt was made to induce abortion at the second month because the patient had aborted not long before, and it was feared that pregnancy had recurred too speedily, while a much desired journey would have to be postponed if miscarriage recurred at the same period as before. Fortunately, the attempt failed, and the patient went to her full term. It was necessary to remind wives and mothers that even spontaneous abortion is often more damaging to health than natural parturition, more frequently lays the foundation of disease, and if repeated, abridges the period of youth and comeliness. These risks were necessarily greater if abortion was induced. The reasons which may be adduced as justifying the induction of abortion are the following: (1) Pelvic deformity so great as to preclude the birth of a viable child. (2) Narrowing of genital canal by tumors, cicatrices, or cancer, so as to prevent the passage of a viable child. Great care was here necessary not to over-estimate the amount of obstruction. If a series of cases of Cæsarean section with fair success should occur, the reasons for inducing abortions in such instances would be undermined. In cases of cancer there was fair ground for this operation, since the woman had but a short time to live in any case. (3) In obstinate vomiting in pregnancy, when all other expedients are fruitless, and a fatal result is anticipated if relief cannot be afforded. (4) In eclampsia abortion should only be induced as a last resort, to save life. (5) In irreducible retroversion or retroflexion of the gravid uterus, but only when life is seriously threatened, not merely because the displacement is irreducible. (6) In severe hemorrhage. (7) In certain other diseases where the complication of pregnancy is undoubtedly endangering life. The responsibility of inducing abortion should never be undertaken without a consultation of two or more medical men, and M. Tarnier had even suggested that a legal declaration should be made to the public prosecutor in every case. He would lay it down that the induction of abortion is only legitimate when the life of the mother is so imperiled by the continuance of pregnancy that emptying the uterus presents itself as the only alternative to save the mother. In insanity, chorea, and the like, the proper treatment was probably to treat the morbid conditions, and leave the pregnancy to take care of itself.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The *Physician's Daily Pocket Record* for 1881, published at the office of the Medical and Surgical Reporter, has the particular convenience that, begun at any time of the year, it holds good for one year from date. All those, therefore, who have not yet provided themselves with a Pocket Record or Visiting List, will find this the most desirable one in the market. Price for thirty-five patients, $1.50; to subscribers to this journal, $1.25

BOOK NOTICES.

How to Use the Forceps. With an Introductory Account of the Female Pelvis, and of the Mechanism of Delivery. By Henry G. Landis, A.M., M.D., Professor of Obstetrics, etc., in Starling Medical College, New York. E. B. Treat, Publisher. pp. 168.

Perhaps no accoucheur, when called in consultation, to aid in a forceps delivery, but has seen, again and again, the absolute want of knowledge, on the part of the medical practitioner, of the mechanism of delivery. Carus' curve is, to many, an unknown land, and as our author forcibly states, the effort is made to drag, by main force, the head through the pelvis, without the slightest regard to the pelvic curves. The forceps, in such hands, become a curse, in place of, as it always should be, a blessing. If every one who aims to practice midwifery will follow th teachings of Dr. Landis, the employment of the forceps will speedily be demanded rather than dreaded, by the parturient woman and her friends.

In order that traction by the forceps shall accomplish all that is required, the author counsels the placing "of the left hand so that the ball of the thumb comes over the locks, while the index finger rests upon the upper arm of one blade, and the middle finger upon the other. Now, while the right hand holds the handles almost at rest, the fingers of the left *push* upon the blades so as to move them and the contained head downward, backward, and a little to the left of the median line. Secondly, while the fingers are pushing downward in this way, we may also make use of them as a fulcrum, and by elevating the handles, cause the blades to move in an opposite manner; but care must be taken that the force thus applied by the right hand is not enough to overbalance the downward pressure of the left, else we will merely extend the head without propelling it." The principle is, that *pushing*, and not *pulling*, is the first step in traction. That is, continued, slight pulling, with elevation of the handles, while the blades are pushed down. Thus the author compels the head to emerge in the line of the pelvic curve. Nor does he find great force required, as of two men pulling at the handles, or the foot braced against the bed. This simple manœuvre of Dr. Landis readily explains the apparently miraculous results observed in the lying-in chamber when two powerful men, having exhausted themselves in futile efforts to extract a head, give way to a skilled accoucheur, who, with but slight effort, accomplishes the wished for purpose.

We are glad also to note his earnest condemnation of the "to and fro," or pendulum movement of the forceps. He justly accredits our townsman, Dr. Albert H. Smith, as having given the best refutation of the fallacy of this method.

We cannot forbear quoting his rule for the time to use the forceps: "Whenever the second stage of labor has lasted two hours, and the head is still stationary, or advancing with great slowness, we should inform the patient that we are about to apply the forceps. If we explain the necessity and propriety of the operation, we will rarely find any objections, especially if the woman is already tired of her fruitless sufferings. This rule may be deviated from, according to the circumstances of each case, but it will more often be proper to shorten it than to protract the time of giving relief. There is no need of keeping the woman in suffering for hours, solely that she may deliver herself; and still less for keeping her under the noxious influence of an anæsthetic for hours, when we can safely extract the child at will."

The book is of decided value as an addition to obstetric lore, and we hope that many will buy it, and profit by its teachings.

Handbook for Coroners, containing a Digest of all the Laws in the thirty-eight States of the Union, together with a Historical Résumé. A Guide to the Physician in Post-mortem Examinations, etc. By John G. Lee, M.D. Philadelphia: Wm. Brotherhead, 1881. Cloth, 8vo, pp. 288.

The author does not claim more for this work than that it is a compilation. In fact, the nature of his subject does not permit much more. The first chapter gives a historical sketch of Coroner's law; the second describes the duties, compensation, etc. of the physician who is called upon by the coroner to aid in the medico-legal researches rendered necessary by a case of death; a third chapter is on the aspects and surroundings of death. The remainder of the volume is occupied by a synopsis of the laws relating to coroners and their duties in the different States; winding up this rather gloomy topic with a little relief in the shape of a dozen pages of humorous anecdotes and descriptions of funny incidents in coroner's courts. It is a volume which all who are occupied with this branch will do well to possess.

The manufacture of the book is not so good as it should be.

Compendium of Microscopical Technology. A Guide to Physicians and Students in the use of the Microscope and in the Preparation of Histological and Pathological Specimens. By Carl Seiler, M.D. Illustrated. Philadelphia, 1881. D. G. Brinton. Cloth. Price $1.00.

In this small book of upward of 112 16mo. pages, containing sixteen illustrations, the author and publisher present to the profession a very handy little compendium of nearly all that is really essential to be learned by the inexperienced who would unravel for himself some of the fundamental truths of histology. It will, we think, very satisfactorily meet a want which the student has often felt when he has attempted, alone and without the guidance of an experienced instructor, to penetrate some of the mysteries of the microscope. As the author states in his preface, other books on this subject, although excellent and indispensable to the advanced student, are far too comprehensive and perplexing, by the redundancy of methods and formulæ recommended, for the beginner.

In the present volume the author has sought to give a clear and concise description of a few

processes which he himself has found to give uniformly satisfactory results. Histological details have very properly been eschewed.

In the first chapter the student becomes acquainted with the essential points of a good working microscope, and learns how to manage the light, the micrometer and the camera lucida.

The three following chapters briefly and lucidly discuss the preparation of animal tissues, the principles of section cutting, and some of the more commonly employed means of differentiating histological elements.

Two more chapters treat, in the same satisfactory manner, of injection of the blood vessels, and of mounting and permanently preserving thin sections and other specimens.

In the last two chapters the author succinctly considers the best methods of preparing vegetable tissues and insects, and some of the physical and chemical conditions for successful photomicrography.

Of course, a little book of so few pages could mention scarcely more than the barest essentials; on the whole, we think the author deserves congratulation upon fairly attaining the object which at the outset he aimed to reach, namely, the production of a useful, brief, clear and practical little guide to the early student of microscopy who would be self-taught.

Finally, we should not forget to commend the publisher for the neat and excellent style in which the mechanical part of the book before us is presented to the profession.

A Practical Treatise on Diseases of the Skin. By Louis A. Duhring, M.D., etc. Second edition revised and enlarged. Philadelphia, J. B. Lippincott & Co. 1 vol. Cloth. 8vo. pp. 644.

The opinion which we expressed of this treatise when it first appeared (in 1876), has been amply borne out by the verdict of the profession. It impressed us then, for the purposes of the general physician, and even for most special students of dermatology, as the most satisfying volume, not only from an American author, but from any author in our tongue. It has, moreover, advantages over any foreign treatise, inasmuch as it describes cutaneous diseases as they are found in the United States, and it is well known they sometimes differ considerably from those prevalent in other climates and continents.

The author has given the present edition a conscientious revision, supporting the results of his own daily extensive observation by frequent reference to the book and periodical literature of his subject, which has assumed very large proportions in the last decade. Indeed, he thinks that no specialty in medicine has grown so rapidly; and though in this opinion we think he may be supported by the specialists of other branches, he certainly has found very considerable additional matter of real practical interest to insert. There are quite a number of new articles; the anatomy of the skin is presented with new lights, and about one hundred pages of matter have been added. Very few sections but have received some editorial attention. As it stands, the volume is an admirable summary of practical dermatology.

Diagrams of the Nerves of the Human Body. By Wm. Henry Flower, F.R.S. Third edition. Philadelphia. Presley Blakiston, 1881. 4to. Cloth. Six plates and text. Price $3.50.

These plates exhibit the origin, divisions and connections of the nerves, with their distribution to the various regions of the cutaneous surface and to all the muscles. They were originally published in 1860, and aim to render the nervous distribution—always a difficult subject—readily understood by those who would acquaint themselves with it. The nerves and ganglia are clearly represented in six plates, printed from stone, each plate being accompanied by a page or more of explanatory text. These plates represent I, II, the cranial nerves, III and IV, the spinal nerves, V, the sympathetic system of nerves, VI, distribution of the cutaneous nerves. The impressions are well made, and no doubt the diagrams will prove quite useful for those fo whom they are designed.

A German-English Dictionary of Words and Terms used in Medicine and its cognate sciences. By Fancourt Barnes, M.D., Lond., etc. Philadelphia, Presley Blakiston, 1881. 1 vol., 8vo., pp. 300. Price $3.00.

Dr. Barnes, in the preface to this dictionary, does not appear to us to give proper credit to Dr. George R. Cutter's similar work, published in 1879, by the Putnams. He has substantially copied the latter, even to the typographical display, and merely inserted a number more words from other sources. He indeed mentions Dr. Cutter's work among others, but does not even give it the first or second place on his list. Many of the words he has added are needless additions, as not particularly or at all medical or scientific, as—to look at the first page only—eel, eagle, kite, superstition, etc. Nevertheless, he has materially added to Dr. Cutter's medical vocabulary, and in a certain measure supplanted it, until the former revises and extends his list.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE EFFORT TO ESTABLISH A BOARD OF HEALTH.

The effort which is making in this State to form a State Board of Health should enlist in its favor the active coöperation of every medical man in the commonwealth. If this is done, this and any other wise and beneficent legislation of the kind can easily be carried through. The medical profession has but to exercise its influence, and represent to every member of the Senate and House the real importance to the community of such a Board, and certainly there will be no material opposition to it.

By such deliberate and general action was secured the passage of the State Board of Health bill for New York. Dr. STEPHEN SMITH says:— "It was determined to rely on the medical profession of this State for the necessary influence to secure the requisite vote in each House to pass the bill." Immediately after the election last fall, the name and post office address of every member elect was obtained, correspondence was immediately opened with an influential medical man in the immediate neighborhood of each member, and he "was requested to take an early opportunity to explain to his representative the necessity of establishing a State Board of Health, and to urge him to support such a measure if introduced into the Legislature." The response to this appeal was unanimous and most cordial, and before the meeting of the Legislature a large proportion of the members elect had expressed themselves favorable to the measure. The next step was to secure the preparation of a proper bill, and the "third step was to secure for the bill the personal care of a competent member of each House." In the meantime petitions were extensively signed by leading citizens throughout the State, and the coöperation of thoughtful persons and favorable newspaper editorials were enlisted, by the circulation of a pamphlet entitled, "Care of Life and Health in the State of New York." And "so the State Board of Health became a law."

The Committee, Drs. W. B. ATKINSON and BENJAMIN LEE, appointed by the Pennsylvania State Medical Society to urge the formation of a Board of Health, have addressed to the profession of the State a circular, which reads:—

> In the interest of the lives and health of our vast population, we beg leave respectfully to urge upon you the importance of bringing your personal influence to bear upon your Senators and Representatives in the Legislature of the State in favor of the immediate passage of a bill to create a State Board of Health. Since the last meeting of the Legislature the States of New York and New Jersey have both taken this important step, and Pennsylvania is now left with a small and rapidly lessening minority of those Governments which still neglect the sanitary interests of their people. We are convinced that a determined and concerted effort on the part of the entire profession is all that is needed to remove this opprobrium, and thus restore our noble State to the front rank of progressive Commonwealths.

It is sincerely to be hoped that this appeal will fall on attentive ears. That this State has not a Board of Health already cannot be called anything short of discreditable for a commonwealth of such intelligence and wealth; and the discredit rests on the physicians of the State, who now have and long have had it in their power, by united action, to obtain it from the Legislative branch of the Government.

No greater economy can be practiced by

commonwealth than to create an efficient Health Board, and give it ample funds and legal authority to protect the health and lives of the community. To prevent disease and to prolong and protect life is to add directly to the wealth of a community as well as to its happiness. To neglect such much needed and obvious precautions indicates great neglect of the true welfare of the State, great ignorance of what that welfare is based upon.

Let this reproach no longer rest upon us; let this excellent measure no longer fail, from the lethargy of the profession.

Notes and Comments.

Porcelain Pessary Twenty Years in the Vagina.

At a meeting of the Societé Medico-Pratique, of Paris, M. Rougon related the case of a woman, fifty-three years of age, who had a pessary introduced twenty years previously. She found so much difficulty and pain in removing it, that after the first three years she left it in place. From time to time she experienced slight pains in the hypogastric and lumbar regions; and there was a sensation of heat with slight discharge from the vagina.

But in 1877 she suffered from acute pain in the lumbar region, with dysuria, which led her to consult a physician, who on examination found the pessary, which he extracted with great difficulty. Examination with the speculum demonstrated the presence of a diaphragm, with central depression, which was all that remained of the os; a uterine sound could be introduced but one centimetre through the opening in this central depression.

Curious Form of Coryza.

M. Bauwens, in the *Journal des Sci. Med. de Louvain*, Dec. 20th, 1880, reports the case of a young man, nineteen years of age, who had a sudden attack of violent headache, accompanied with a feeling of weight and stoppage in the posterior nares. Then, after a fit of sneezing, there supervened an abundant flow of serous liquid from the nostrils; this lasted for three or four hours, the liquid becoming thicker.

After this attack he suffered from the same at first every third day, and later on every day, and even twice a day; the attack was always the same and there was no fever; rhinoscopic examination revealed a congested state of the Schneiderian mucous membrane, but no ulcerations or polypi.

Astringent injections of every description, as also of solutions of chlorate of potash, proved of no benefit, and it was determined to try sulphate of quinine, on account of the periodicity of the attack. For four days there was no attack, but the benefit was but momentary.

Arsenic was then given, in doses of 1 milligram gradually increased to 1 centigram, and the success was immediate. There has been no access for three weeks, and there exists no longer any trace of inflammation of the olfactory mucous membrane. Trousseau has cited cases where similar attacks of coryza alternated with the habitual manifestations of asthma, but the success of arsenic in this case would seem to prove for M. Bauwens that the periodical attacks were a manifestation of intermittent fever (forme larvée) particularly as there existed no antecedents pointing to the existence of any asthmatic tendency.

Hemorrhagic Pleural Effusions.

In a recent monograph on this subject, by Dr. Charles Nélaton (of Paris), he gives the following as the conclusions at which he has arrived:—

(*a*) Effusions of blood into the pleuræ may be due—1. To a lesion of the vessels of the thoracic walls (the intercosto-mammary). 2. To a lesion of the intra-thoracic vessels. In the latter case the hemorrhage is generally furnished by the arterial branches which accompany the bronchi, of the second and third magnitude.

(*b*) Respiration favors the hemorrhage. The accumulation of blood in the pleural cavity quickly arrests the hemorrhage.

(*c*) The effused blood coagulates entirely and immediately; it then separates into two parts—coagulum and serum.

(*d*) If the effusion is not very abundant the serum is re-absorbed within three or four days, and when the phenomena of inflammatory reaction supervene, they centre round the coagulum, and finally encapsule it.

(*e*) If the quantity of the effused liquid is very great the exuded serum is not absorbed at the time when the inflammatory reaction comes on. Then the remaining serum becomes altered, and its presence gives rise to accidents.

(*f*) The symptoms and prognosis of the hæmothorax are not identical in the two cases. In the former case the prognosis is favorable; in the latter it is grave.

(*g*) The treatment of the cases also differs.

For the former class of cases occlusion should alone be practiced; for the latter class the pleural effusion must be evacuated.

(*h*) Capillary aspiration may be tried first.

(*i*) If the fluid so drawn out be purulent, or if its flow be imperfect, the operation for empyema must be undertaken.

Preserving Subjects for Dissection, Etc.

From the appearance of the subjects in the dissecting rooms of our best medical colleges, some simple but effectual method of preservation would seem to be urgently needed.

M. Hairion, in a report on the medical Section in the last Paris Exposition (*Journal des Sci. Med. de Louvain,* November, 1880), speaks of the different systems of preservation on exhibition:—

1. Laskowski injects into the arteries glycerine and carbolic acid, and his preparations remain in a fit state for dissection for six or eight months.

2. Prof. Efisio Marini, of Naples, presented admirable dry preparations, which on immersion in a certain liquid become softened and appear fresh, having the natural color of the various tissues. In another preparation putrefaction had been arrested after the twentieth day. These preparations received the approbation of MM. Nélaton and Sappey. Unfortunately Prof. Marini's method is kept secret, but there is no reason to suppose that it differs essentially from that of Dr. Wywodzoff, chief surgeon of the St. Petersburg military hospital, who embalmed the body of Anson Burlingame, which was found in excellent state of preservation several years later.

Dr. Wywodzoff makes as few incisions as possible, and does not open the cavity of the abdomen or of the thorax. He opens only the carotid and crural arteries, and after many experiments has arrived at the following conclusions:—

1. The best liquid to inject an entire subject, a limb, or a visceral organ, is the following solution:—

WYWODZOFF'S FLUID.

℞.	Glycerine,	4 pounds.
	Water,	2 pounds.
	Thymol,	3 grams.

2. A quantity of liquid about one-half the weight of the subject is necessary.

3. The liquid should be slowly injected; if one limb is to be injected, the denuded part should be immersed in boiling water and the medullary canal stopped up with a cork.

4. The veins accompanying the carotid and femoral arteries, the jugular and femoral, should be opened near the openings in the arteries and the liquid injected until it appears in these veins.

5. When the liquid commences to pass by the mouth of the subject, the trachea must be opened, a cork inserted and a stout ligature applied.

6. When the capillaries of the skin are filled, the operation may be considered as finished; if one of the limbs should appear not well done, it should be separately injected.

Men as Nurses.

The *Lancet* represents what may be called the hide-bound conservative English medical opinion. Not only does it scorn women as doctors, but now it intimates that they are not much as nurses. In the issue for December 11th it says, editorially:—

"It is a mistake to suppose that women are necessarily the only good nurses. In the opinion of some persons who claim to be judges of the question, they are neither so quiet, so self-possessed, so precise, nor so strong as men. It is alleged that no man who has been nursed by a gentle-handed male servant would desire, in any subsequent illness, to be attended by a female. It is said that whatever element of the female character or influence is desired in the sick chamber, can be best contributed by the presence of a mother, a wife, or a sister. When the circumstances exclude these forms of the luxury it can seldom be a necessity. If the employment of men to nurse men were encouraged a great difficulty would be surmounted, and a good social reform begun. The whole subject is one of pressing interest, and the hints we have now thrown out are intended to state the question rather than to discuss it. There is urgent need to uproot growing prejudices, and to amend grave errors and misconceptions to which special circumstances have given rise."

Dry Cupping in Typhoid Fever.

Dry cupping was recommended in 1857, by Behier, in cases of typhoid fever where the thoracic complications were predominant.

In a recent article in the *Journal de Med. et Chir. Prat.*, M. Huchard has shown, by numerous observations, that dry cups may be employed with benefit in very many cases of dothienenteritis.

He uses them in all, except very benign cases; typhoid fever is essentially a congestive disease; lungs, kidneys, intestines and even the brain are loaded with blood, and this state must be energetically combated. Dry cups act by derivation,

rendering the capillary circulation more active; substituting cutaneous congestion for active vis. ceral hyperæmia; under their influence, the general condition improves, there is less stupor; in certain cases, even, there is a fall of temperature. M. Huchard has followed this course of treatment for two years, and cases at present in his service demonstrate the good results of the treatment.

The cups must be freely applied twice a day, morning and evening; twenty or thirty must be applied at the lower posterior part of the chest and on the abdomen; they must be left in place a quarter of an hour. The application is often painful in regions where there is little cellular tissue under the dermis, but the advantages drawn from the treatment more than counterbalance this drawback.

Correspondence.

Product of Cow Vaccination.

Ed. Med. and Surg. Reporter:—

The prevalence of smallpox in your city at this time revives the interest in a mooted question—namely, the relations of variola and vaccinia.

In the first editions of his work on the practice of medicine, Dr. Flint says that vaccine virus may be and has been obtained by inoculating the cow with variolous matter obtained from the human subject, and that the matter thus obtained will, when inoculated into the human subject, produce the true vaccine disease.

You have, on more than one occasion in the last few years, denounced this as a dangerous error, in your journal, and Dr. Flint himself, in the later editions of his work, has recanted the opinion formerly expressed.

But now comes Dr. Edward Cator Seaton, in "Reynold's System of Medicine," who says the "common origin of smallpox and cowpox may be considered as established."

He cites no less than six instances, where vaccine virus has been obtained by inoculating cows with human variolous matter, concluding with that of Mr. Badcock of Brighton, England, who, he says, succeeded in thirty-seven separate occasions in obtaining genuine vaccine lymph by inoculating cows with the lymph of human variola.

I think it will be a matter of much interest to your readers to have your present opinions on this subject. Richard Dingee, m.d.

Newportville.

[We have submitted this question to several experts in the matter, for instance, to the late Dr. B. Rush Senseny, who, we believe, made an experimental investigation of this subject, and they all agree that lymph from the vesicle on a cow produced by vaccination with humanized virus is not effective; nor does the cow exhibit the same symptoms as when inoculated with vaccinia. We are always desirous of new light, however. Mr. Seaton is not an authority on bovine virus. Ed. Reporter.]

Weights and Measures.

Ed. Med. and Surg. Reporter:—

For many years I have been noting the use and advancement of the French weights and measures; especially so far as they are applicable in writing prescriptions. And with no fault to find, provided that we are French.

It is evident, however, from the past, that it will be a long way down through the centuries before they will be adopted generally by English speaking peoples, and perhaps never.

The grain, minim, etc., have come to be ineffaceable upon the English brain; and it seems somewhat unfortunate, too, that none of our weights and measures can be expressed by that system without a fraction.

Might not a change be made, though very slight, which would render our method of prescribing much less objectionable, as well as equally simple and accurate? I have so concluded. First, by discarding the scruple altogether, and also the signs ʒ and ℈ in prescribing, thus avoiding a confusion which has led to so many serious errors. Secondly, by expressing all quantities entering into prescriptions in grains and minims, provided that they shall be so grouped as properly to represent grains, minims, drachms, ounces, etc.

Let X, Y, Z, be the signs—

Thus $X^d_g j$=1 gr. $Y^d_g j$=60 grs. or ʒ. $Z^d_g j$=480 grs. or ℈, and $Z^d_g xij$=5760 grs. or ℔.

And $X\mathfrak{m}j$=1m. $Y\mathfrak{m}j$=60 ♏ or fl. ʒ. $Z\mathfrak{m}j$ =480 ♏ or fl. ℈, and $Z\mathfrak{m}xvj$=7680 ♏ or O. Further explanation is unnecessary. *e. g.*

℞. Ferri et quiniæ citratis, $Y^d_g ij$
Acidi citrici, $X^d_g xx$
Aquæ calientis, $Z\mathfrak{m}ij$
solve. deinde adde
Aquæ, q.s. ad. $Z\mathfrak{m}iv$. Agitans.

Sig.—Dose, 60 minims, after meals, in anæmia.

℞. Antimonii et pot. tartratis, $X^d_g v$
Morphiæ muriatis, $X^d_g iv$
Extractum ipecac. fluidum
Ex. hyoscyam. fluidum, āā $Y\mathfrak{m}iiiss$
Aquæ, q. s. ad. $Z\mathfrak{m}v$.
Agitans.

Sig.—Dose, a teaspoonful every 3 or 6 hours, in obstinate cough.

Geo. Hill, m.d.

Hughesville, Pa., Feb. 9th, 1881.

Vomiting in Pregnancy.

Ed. Med. and Surg. Reporter:—

Some time since I was called to see a Mrs. R. who was afflicted with vomiting in pregnancy to such an extent that she could eat nothing. I gave her about all of the usual and well-known remedies and methods of relief, with no benefit whatever.

Another m.d. was called in and tried all of his skill with no benefit, when I was again called. I found my patient emaciated and dropsical, with œdema of legs and feet, in fact, reduced to a pitiable condition. I had exhausted the resources

of the materia medica, to such an extent that I was at my wits' end, as to what to give or do, and in my dilemma prescribed comp. cathartic pills. U. S. P. formula. I did not hear again from my patient for several weeks, when her husband visited my office and wanted another box of the pills. His wife, he stated, had been perfectly relieved from the first dose of the pills, and an occasional dose kept her perfectly well and entirely free from the sickness.

I recommended the same remedy to another physician who detailed a case to me in which everything he had tried had failed, and miscarriage had threatened. He reported his case perfectly relieved of her sickness by the pills, and also of her threatened miscarriage. She had had three successive miscarriages previous to this time. I have no doubt but this simple remedy will relieve a large majority of these obstinate cases of vomiting; it will at least relieve those cases caused by reflex action, produced by pressure of feeal matters on the gravid uterus.

Grove City, Ill. J. G. HARVEY, A.M., M.D.

Dysmenorrhea.

ED. MED. AND SURG. REPORTER:—

I have for some time past treated cases of dysmenorrhœa as follows, with very satisfactory results.—

℞. Iodidi potassii,		
Bromidi potassii,	āā	ʒ j
Syr. simp.,		ʒ iij.

A teaspoonful to be taken three times daily, commencing ten days previous to menstrual period.

When pain commences—

℞. Tinct. opii camph.,	ʒ ij
Morph. sulph.,	gr. ij
Ol. piper.,	gtt. ij.

A teaspoonful every three or four hours while pain continues.

The above has proved very satisfactory to me and may be worth something to others, as I have seldom had to repeat the course more than once to effect a permanent cure. I. W. PEARSON, M.D.

York Springs, Pa.

NEWS AND MISCELLANY.

Interference Acts.

The following extraordinary acts have been introduced before the Pennsylvania Legislature, and we are informed by a responsible gentleman that they are strongly urged, and may possibly pass. Let not this folly be committed:—

AN ACT TO REQUIRE PHYSICIANS AND OTHERS TO WRITE THE NAMES OF MEDICINES IN THE ENGLISH LANGUAGE ON THEIR RECIPES.

WHEREAS, Grievous errors and mistakes have been made by druggists and others in the compounding of the prescriptions of physicians, by reason of the same being heretofore written in the Latin tongue and in abbreviations thereof, as well as the quantities or proportions of the drugs or medicines being designated therein by figures or symbols in a mode not readily understood by the bulk of the people, whereby undue advantage and a mystification of the patients may be taken by unscrupulous doctors, druggists and persons who prescribe or compound medicines for the sick and poor, and it being desirable to simplify the practice of medicine, and to enable the public generally to better comprehend the names and nature of such drugs; therefore—

SECTION 1. *Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in general assembly met, and it is hereby enacted by the authority of the same,* That physicians and all other persons engaged in prescribing medicines or drugs for the sick, shall write the names, quantities and designations of the same plainly, in the English language, and without abbreviations; and a copy of such recipe or medicines so compounded by druggists, herbists or any other persons shall be labeled or written on the outside of the bottles, vials or packages containing the same.

SEC. 2. That any persons violating the provisions of this Act shall be guilty of a misdemeanor, and on conviction before a magistrate, alderman or justice of the peace of the county where such offence may be committed, shall be subject to a fine of twenty dollars for each offence, together with costs; and in default of payment, to an imprisonment of not less than ten days, or more than twenty days, at the discretion of the court.

SEC. 3. This Act shall take effect immediately.

AN ACT TO REQUIRE DRUGGISTS AND OTHERS TO LABEL THE BOTTLES, ETC., OF MEDICINES IN THE ENGLISH LANGUAGE.

WHEREAS, Serious mistakes and confusion in the sale and compounding of medicines for the sick have occurred by druggists and others, by reason of the names thereof being written or printed in the Latin tongue; therefore

SECTION 1. *Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in general assembly met, and it is hereby enacted by the authority of the same,* That all druggists, vendors or compounders of drugs, medicines or herbs for the use of the sick are hereby required to label or print the names thereof conspicuously on the outside of the bottles, pots or packages containing the same, in the English language and without abbreviations.

SEC. 2. That any person violating the provisions of this Act shall be guilty of a misdemeanor, and on conviction before a magistrate, alderman or justice of the peace of the county where such offence may be committed, shall be subject to a fine of ten dollars for each offence, together with costs; and in default of payment, to an imprisonment of not less than ten days, or more than thirty days, at the discretion of the court.

SEC. 3. This Act shall take effect immediately.

We have not learned who the parent of this absurd legislation is.

National Association for the Protection of the Insane and the Prevention of Insanity.

We have been requested to state the scope and object of this Association, which was organized last summer, and held a meeting at Cleveland,

Ohio. Its purpose may be understood from the following quotation from the circular then issued.

"There are multitudes of insane men and women in the United States for whom no special provision is made in the way of care and treatment. Occasional legislative and other investigations have brought to light the misery and suffering that this absence of special care and treatment has produced. Furthermore, even when it has been supposed that this has been secured by the establishment of State, County, and City insane asylums, these have sometimes failed of their purpose, through mismanagement, or a misconception of the proper methods to be used. Thus there is room for organized effort to improve the condition of the insane. Again, inasmuch as each State has the exclusive control of the policy and the mode of management of the insane within its borders, it would seem as if such organization were desirable to unify the principle and the practices in the care and treatment in the United States generally. Two other organizations may, perhaps, be supposed to cover the same field with the new society.

"The Association of Superintendents of Insane Asylums was established with somewhat similar ends in view. But this is strictly a professional and technical organization. It includes only the Medical Superintendents of insane asylums, and it is safe to say that their interest in the insane bears no greater proportion to the public interest in the same class, than their membership bears to the vast number of the insane under treatment, together with their families and friends.

"The Conference of Charities, which has been working in the same direction, falls short of covering the whole field, in the fact that it is commensurate only with the States where Boards of State Charities exist, and also because its energies are scattered over the whole ground of the dependent and criminal classes. This National Association, then, by confining its labors to a single class, but the whole of that class in the United States, wherever situated, may reasonably hope to accomplish more in the line of its purpose than the others named, especially if cooperating with them in the general aims. It solicits, therefore, the general coöperation of all friends of the insane, and all interested in the subject, whether connected with the other organizations named, or among the public generally."

At this meeting the following officers of the Association were elected: H. B. Wilbur, M.D., Syracuse, N. Y., President; Nathan Allen, M.D., LL.D., Lowell, Mass., Vice President; Miss A. A. Chevaillier, Boston, Mass.. Secretary; George M. Beard, M.D., New York, N. Y., Treasurer.

Is Cold Favorable to Health?

In his last report as registrar of Providence, Dr. Snow writes:—

"There is a popular error, which we often hear spoken of in the winter season, that clear, cold weather is favorable to the public health. The truth is, that *in this climate* severe cold weather, if continued more than two or three days, increases the number of deaths as certainly as continued hot weather, though in a different manner. Severe cold depresses the vital forces, and exposure to it produces fatal results among those persons, or classes of persons, whose vital force is weakened by any cause. Such persons are the aged and the very young, and also all who are sick or debilitated from any other cause. Besides this, severe cold is no preventive of, but on the contrary, is favorable to the spread of some of our most fatal diseases, as smallpox, diphtheria, and scarlatina. This is shown at the present time in Brooklyn, New York, Philadelphia, Chicago and other places."

"Dr. Buchanan."

Judge Allison declined, on February 12th, to sentence Dr. Buchanan, the "diploma vendor," for the crimes to which he pleaded guilty in the Quarter Sessions. He was then under indictment in the United States District Court, upon which he was sentenced to the Eastern Penitentiary, and, added his Honor, it is now impossible to sentence him to the County Prison, as he cannot at one and the same time be imprisoned under sentence in the Eastern Penitentiary and the County Prison.

Dr. Charles H. Kehnroth, who pleaded guilty, some time ago, to selling academic degrees, was sentenced, on the same day, to twelve months' imprisonment.

Items.

—On February 22, Dr. William Pepper was formally inaugurated as Provost of the University of Pennsylvania.

—We have a number of letters from physicians in different sections condemning the effort to force the metric system upon the profession.

—At an annual dinner of the Baltimore Med. and Surg. Soc., Jan. 26th, 1881, Dr. J. J. Caldwell recited an interesting poem on "The Triumphs of Science."

—A young Russian lady, who was studying medicine in Paris, committed suicide, in December, by firing off a revolver through her head. Death was instantaneous; and it was ascertained that the despair of passing her examination, which was to come off the next day, was the cause of the melancholy event.

—An ingenious philanthropist proposes to diminish the mortality among the wounded in war by tattooing on the soldiers' bodies the principal points where compression may be made in cases of hemorrhage. Life may be lost in a few minutes by a wound of a large artery, and it is thought the soldier might often escape if he knew where to command an artery while waiting for help.

—Dr. J. T. Reeve, Secretary of the Wisconsin State Board of Health, writes us that the alleged presence of smallpox in Wisconsin is an error. Only one case has been reported in Wisconsin, and effective measures have been taken with that. The Board has issued a circular impressing on the people the importance of vaccination.

OBITUARY NOTICES.

—Dr. Allison E. Perrine, a brother of Quartermaster General Perrine, died Feburary 7th, age 75 years, at his home, a few miles from Trenton, N. J.

—Dr. William Trevitt, a prominent citizen of Columbus, Ohio, ex-legislator and ex-Secretary of State, is dead, at the age of 82 years. He was surgeon on the staffs of Generals Taylor and Wool, of the Mexican War, consul at Valparaiso and afterward at Callao, under Buchanan.

—Dr. Edward A. Page, who had been a practicing physician and surgeon for thirty years, died February 18th, at his residence, No. 1415 Walnut street, from disease of the liver, in the fifty-first year of his age. Deceased rendered valuable service as an army surgeon during the war, and afterward resumed his practice in this city. He was medical director of the Penn Mutual Insurance Company, and was connected with St. Joseph's and other hospitals.

—Dr. Edward S. Bell, of Zanesville, Ohio, died in January, at an early age. The Zanesville Academy of Medicine passed resolutions of respect to his memory, in which they say:—

"The death of our accomplished young friend, Dr. E. S. Bell, can fairly be traced to his excessive devotion to books, to the bad air and his self-sacrificing attentions to the sick in hospitals, and to malarial and septic poisoning: in truth, his life was another sacrifice to science and humanity."

—In December, in Rio de Janeiro, a Professor of the School of Medicine, Dr. Louis Pientzenauer, committed suicide while the bailiffs were in his house executing a distress for rent. The fact caused an extraordinary sensation. His salary was about $2500 a year, but it appears that his private practice was very small, and the expenses of living in Rio are enormous. He was separated from his wife, but left an octogenarian mother and four children. Subscriptions have been opened for the benefit of the family, the Emperor and Empress having both contributed.

—Dr. James O. Pond died in New York city last week, at the age of 90 years. Dr. Pond was a native of Torringford, Conn, where he lived for nearly thirty years. He graduated from the medical department of Yale, and first practiced his profession in his native town. He represented Torringford for several terms in the Connecticut General Assembly, and at one time, while President of the Senate, became, temporarily, the acting Lieutenant-Governor of the State. He came to New York City in 1829 or 1830, and opened an office in the neighborhood of Carmine street. While in that part of the city he was called by a friend to participate in making an autopsy on the body of a 'longshoreman. The popular feeling against dissection was at that time so strong that, the matter becoming noised abroad, great crowds collected about the house where the autopsy was to have taken place, and a riot was imminent. Through the efforts of the militia and Bishop Dubois, violence was prevented, and Dr. Pond and his friend escaped injury, but their residences were specially guarded for several days, so determined were the 'longshoreman's friends on revenge for what they considered at least an insult to humanity. Dr. Pond subsequently became the treasurer of the New York Academy of Medicine, which position he held for many years.

QUERIES AND REPLIES.

Dr. A. N. Dougherty, Newark, N. J., on the results of aspiration and of free incisions in the treatment of chronic emphysema. He will be glad to receive statistics and cases from any member of the profession.

MR. EDITOR.—In No. 6, February 5th, 1881, is a reply to "Sicurus," in your medical and surgical journal, concerning a plant with the name of *hermodactyl*. The orthography of this word is, in German, *hermodatteln*, in English hermodates—and means the bulbous roots of Iris Germanica, belongs to the family Irideæ, used in old times as a diuretic, by Hydrops, etc.

Yours, respectfully,

Mahanoy City. PHILIP WEBER, M.D.

Dr. T. B. T., of O., would like suggestions for the treatment of an obstinate case of chorea in a girl eight years old. All ordinary plans have failed

Dr. E. N., of S. C., asks: Can a fœtus at two months' gestation receive the infection of measles and it lie dormant till after birth, and then the infant have a well-developed case of measles?

Dr. E. D., of Pa.—We cannot find that the instrument you inquire about is still manufactured. It seems to have been superseded.

Dr. P. P. A., of Miss., asks whether there are any means by which the female breast can be developed. Many ladies are greatly grieved at the atrophy of the gland after nursing, and if there are any hygienic measures by which the symmetry of the form could be restored, he should like to learn of it through the REPORTER.

Dr. M., of Tenn.—Dr. Leonard mentions various depilatories, but none free from serious objections.

Dr. H. A. A., of Ala.—The "liver regulator" you inquire about has not, we believe, been analyzed.

MARRIAGES.

ALBA—GUNDAKER.—At Newark, N. J., January 31st, 1881, by Rev. S. L. Baldwin, D.D., Rev. Francis Taft Alba, M.D., and Mrs. Emma Scheerer Gundaker, all of Newark.

BECKWITH—HUNTER.—In New York city, on Thursday, January 13th, 1881, by Rev. Thomas S. Hastings, D.D., Frank E. Beckwith, M.D., and Miss Rachel B. Hunter.

OWENS—FOSTER.—On January 13th, 1881, at the residence of the bride's parents, Ashland, Schuylkill Co., Pa., by the Rev. James Robinson, Pastor of the First Presbyterian Church, Dr. Wm. R. Owens and Miss Lillie Foster, all of Ashland, Pa.

DEATHS.

BARTLETT.—In New York, on Saturday, February 5th, Rodman Bartlett, M.D.

PERRINE.—In Lawrence Township, N. J., on the 6th inst., Allinson E. Perrine, M.D., aged 75 years.

POND.—In New York, on Tuesday, February 1st, Dr. James O. Pond, aged 90 years.

SMATHERS.—Of scarlet fever, on January 30th, Mary Myrtle, only daughter of Dr. W. J., and M. C. Smathers, of Du Bois, Pa., aged 4 years, 8 months and 16 days.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

VALVULAR DISEASES—HYPERTROPHY.

BY ALONZO CLARK, M.D., LL.D.,

President and Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons, New York.

(*Continued from page* 230.)

I have some curiosities here, some that are so rare that you may never see anything of them, and some that you will see plenty of. Here, for example, is a heart, the pericardium of which is attached to the heart, but between the pericardium and the heart is a layer of bone that makes a perfect hoop, or did make a perfect hoop, about the heart. I have heard of people having to be hooped to avoid splitting, but never of a hooped heart. This bony material, you observe, is covered over by the pericardium on the outside, and attached to the heart on the inside. It comes around here, flattens out here to make quite a broad covering, then it grows narrow, and is broken at this point—you will feel the rough bone on each side—it then goes on up to the point of starting. How a heart hooped in this way could pump out blood is a matter of wonder. It was probably by a change in its usual motion. The contraction was probably from the point toward the base. There is also here a considerable amount of thickening and hardening of the aortic valves, but not so much as in some specimens I shall show you. The amount of effusion that took place during the pericarditis, between the pericardium and the heart, was too large to undergo organization, and for some reason, bony matter has taken its place. It was very likely broken down and absorbed in part, and a calcareous matter is deposited, in the fashion you see.

Here is a heart that I shall have occasion to refer to, perhaps, at our next hour. Observe particularly its flabbiness, but more its color, yellow—compare it with other hearts on the table—its yellow hue. This is not so very deeply marked, however. It is a fatty heart. It is Quain's degeneration. It is a feeble heart also; the walls are hardly of the usual thickness. But I will touch on this again further on.

As I shall have something to say about hypertrophy of the heart soon, you may now examine these hearts. In this one you observe the left ventricle is enlarged. The dilatation is equal to the hypertrophy. The right heart has undergone but little change. Observe, it is not larger than the ordinary size. I call your attention particularly to the valves now; observe, they are thickened, shortened and stiffened.

Here is quite a little heart which contained, at one time, in its left auricle, which you observe is hypertrophied, a false membrane; a disease of the heart which I alluded to when speaking of common endocarditis. But the false membrane has all been pulled off by experimenters, and handlers, but this is the heart, and you will observe very marked stenosis, with calcareous degeneration of the mitral valve. You can hardly get your little finger through it.

I have but little more to say regarding valvular diseases. I told you that the valves are occasionally torn out; the aortic valves are torn out at the bottom, at the attachment to the aorta. The cup is made no cup by having its bottom fall out, so to speak. That is almost always the consequence of atheromatous degeneration, weaken-

ing the valve at that point. There is another atheromatous change that is met with occasionally, and that is atheromatous deposit at the point where two of these valves are together attached to the aorta. You will observe as you examine these specimens, that each pair of the valves, each of the two valves that are near to each other, have their attachment to the aorta at the same position; that is, one is in immediate apposition to the other. Now, it sometimes happens that the aorta at that point gets atheromatous deposit, and it happens that that attachment has been torn down. It is torn down so that the attachment comes to be ab ut a quarter of an inch below the attachment of the other valve, and this produces insufficiency. The valves will not, even suppose they are not diseased, meet in the middle of the aorta; one will fall in below the others, and consequently the valve is incomplete —insufficiency, in other words.

These, I think, with those enumerated before, will constitute the changes which you will be most likely to meet. Possibly not all the changes, but they are all that occur to me as occurring with any degree of frequency.

There is a point which I omitted to refer to, but was reminded of by one of the students, and that is with regard to the pulse in regurgitation at the aortic opening. There is a peculiar pulse. It has not, as our Methodist friends say, *the gift of continuance.* It is a blow, and then nothing—short, sharp, I cannot say decisive. It seems as if the pulse is instantly cut off as soon as you feel it. There is a little duration to the swelling of the artery in the healthy condition, and still more in hypertrophy of the heart. Supposing there is no obstacle, but if there is regurgitation at the same time, the pulse has that short, quick, sudden beat and sudden subsidence; the force that created the pulse seems to be withdrawn instantly after you feel the pulse, and then there is not infrequently, on account of the smaller wave of blood that is sent out, a little retardation; that is, the pulse does not come to the finger as soon after the heart-beat as in health. But that you can only appreciate by putting one hand on the præcordial region and the other on the pulse. The arteries in the neck, in instances of hypertrophy and regurgitation at the aortic opening, are apt to be enlarged, and to have a wider beat. You observe I do not say *stronger* beat, but a wider beat than usual, and the pulse in them is apt to be feeble; and further, the arteries in time not infrequently grow tortuous, they wind about instead of going direct to the point of distribution.

In regard to the treatment of valvular diseases, it is so entirely bound up in the general subject of treatment of cardiac diseases in general that it does not require attention at this moment. The question will naturally occur to you, how much havoc can be made by these diseased valves? How dangerous is it? The reply would be this: Obstruction at the aortic opening is the least dangerous of all, because of the compensation that can be furnished by the hypertrophy of the heart. Obstruction at the mitral opening will be grave or not, depending upon its extent. As I told you, one day it may become a very grave matter, producing a cyanosis that may be visible in the face, a congestion of all the important organs of the body, and leading to rather a slow death, that is, an illness that may be protracted through several months, or half a year, or even a year, and finally death, perhaps not so soon as the patient desired it. But diseases of the mitral valve usually have a slow ending through affections of the kidneys and dropsy, particularly œdema. Regurgitation at the mitral valve goes in the same class; it stands with obstruction of the mitral valve in regard to its mode of termination; that form of disease that is most likely to have a sudden termination, that condition in which the patients are sometimes told they may drop down dead in a moment, which is a very unwise thing to tell a patient, it makes him anxious all his life, fearing at every moment he may drop down dead. It is a very proper thing to say to such a man, we are, any of us, liable to drop off, we do not know when, and in health is the time to arrange one's business for death. And especially in New York should the wealthy make a will, since the administrators, if there were no will, would have to get security in double the amount of the estate. Suppose Cornelius Vanderbilt had died without a will, how could his estate be administered? Who could go security for thirty or forty millions of dollars—double the amount, in two securities. This is a fact that it is important you should know as medical men, because you may do a good deal of good to families by giving them, not exactly a warning of their deaths, not write down in the almanac the day they must die, but tell them, if they have property, to make a will, no matter how well they are; the better the health the better the will. The condition that is most likely to be attended by this sudden result is regurgitation at the aortic opening, by a return of blood into the ventricle after it has once entered the aorta. You can easily see that in this case, depending upon how much regurgitation there is, there will be a diminished

quantity of blood circulating in the arteries of the body. The brain will not receive its due amount, and syncope may take place, you cannot say when. It does not require a very grave lesion of this kind to lead, in certain instances, to sudden death, and it almost always occurs by a sort of syncope, the brain receiving too little blood to stimulate it to proper action, and to react upon the heart. The heart ceases to beat and the patient is dead. And yet do not give these patients unnecessary alarm. They may carry this lesion that leads to regurgitation from the aorta into the ventricle for a great many years. The number of instances in which persons die with this lesion suddenly, compared with those who die a lingering death, is very small. It is an old error to suppose that persons who have cardiac disease must die suddenly. They may, and others may. A good many years ago, when I was just entering upon the profession, I took up the study of the cause of sudden deaths; and one of the first that occurred, which I studied, was of a young woman in Bellevue Hospital. She had had typhus fever. It was in 1847. I was not so young in the profession as I was thinking. Well, typhus fever was prevailing there to a remarkable extent. She had got through with her typhus fever, and was in a condition of convalescence. She got able to go about the wards and take care of other patients to a certain extent, but she felt a little weary at times. After eating dinner she had lain down upon her bed and taken a nap. Another patient, her next neighbor, had done the same thing. She woke from her nap, raised herself in bed, and said to her neighbor, "I have not felt so well as I do at this moment since I was first taken sick," and had scarcely finished the sentence when she fell back senseless, dead. At post-mortem examination we found there was an effusion of blood at the base of the throat, involving all the nerves of respiration, compressing them to a certain extent, so that the respiration stopped suddenly. In following up the inquiry, I found within six months six cases of the same kind. Since then I have not seen one. Sudden death, then, has a variety of causes. In a person who is known to have cardiac disease it is usually ascribed to that affection, but it is not a matter of course that it will be so. And then you are to bear in mind that in certain forms of disease of the heart there is greater danger at the brain than there is at the heart itself. That is, hypertrophy of the heart without obstruction is a rather frequent cause of apoplexy. An hypertrophy of the heart without obstruction between the arteries of the brain and the heart itself is apt to lead to apoplexy. With these remarks, then, on the relation of valvular disease to life, I leave that topic at present and call your attention to hypertrophy of the heart.

When I was a student of medicine hypertrophy was described under three divisions: First, simple hypertrophy; Second, eccentric hypertrophy; and third, concentric hypertrophy. We do not use those terms now. It is hypertrophy, and hypertrophy with dilatation. Hypertrophy with contraction, concentric hypertrophy, is probably, in every instance, no hypertrophy at all. The last act of the heart was to contract, and to force out the blood that was, just the instant before, within its cavity. It is very much contracted, its cavity is nearly obliterated, and it may be taken for a diseased condition. But it is a natural office of the heart to contract, and if death strikes at the instant the contraction is completed you will, of course, find no blood in the ventricles of the heart; you will find it smaller than natural, and that would not be consistent with the term hypertrophy. The walls are thicker, because they are contracted. I think it would be found that every instance that was of old called concentric hypertrophy, could be resolved into the condition that I have described. So that now we have hypertrophy, and hypertrophy with dilatation.

The first question that presents itself is, what is hypertrophy of the heart? Well, the obvious answer is, enlargement of its walls; increase in the bulk of matter that constitutes the walls of the heart. Well, what constitutes the walls of the heart? Mainly, muscular fibres, and some connective tissue. Then it is the muscular fibres of the heart that are increased; and how increased? I asked myself that question a great many years ago, and I resorted to some old specimens and to others I found at the hospital for the answer. A point to be investigated was, the size of the muscular fibre in hypertrophy of the heart; is it larger than the muscular fibre in the heart of natural size? I procured about twenty or twenty-five, and drew fibres from different parts of the heart, from one ventricle, and then from the other, and compared those from the natural heart with those from the hypertrophied heart, and though occasionally I would find an enlarged fibre the average was pretty nearly the same in the healthy and in the hypertrophied heart. Well, then, the conclusion is inevitable, that if the same proportion exists between the size of the muscular fibre of the natural and of the hypertrophied heart, there must be a

multiplication of the fibres of the muscles in the latter, and that is a fact. There is a new production of muscular fibres. From what origin they spring I cannot tell you, but nature has so arranged it that if the heart needs additional strength it can get additional fibres.

The size to which the heart may grow is, perhaps, limited to sixty ounces. When we meet next I intend to show you one that weighed fifty-seven ounces—within three ounces of the largest heart the weight of which has been recorded. The natural weight of the heart in a full grown person, not remarkably broad upon the shoulders, is eleven ounces; if, then, it is increased to sixteen or eighteen ounces, you see there is some hypertrophy; if it is increased to twenty-five or thirty, there is very considerable hypertrophy; and if it is increased to anywhere in the neighborhood of sixty ounces it is *cors bovinum*, an ox heart. And here I may say that that enormous size is never attained except in persons in whom disease of the heart began in infancy. This, the largest heart I possess, perhaps the largest heart in the country, was taken from a man who, at six years of age, was taken over by his physician, from Randolph, Vermont, to Dr. Nathan Smith, and was shown by him as an instance of heart disease arising from inflammatory fever, rheumatism. The boy had had articular rheumatism, and his heart became involved, and Dr. Nathan Smith had interest in it as an instance showing there might be some connection between articular rheumatism and disease of the heart. It was fourteen years after that—more than that—twenty odd years, before Buillot made out a connection between articular rheumatism, pericarditis and endocarditis; so that, really, had it been published, that discovery of Dr. Smith would have been put first, as showing the relation between rheumatism and inflammatory affections of the heart. The boy grew up, attained the age of twenty-eight years, and to show you his was not a useless heart, he was foreman of a manufactory in the immediate neighborhood of Springfield, Massachusetts. He was only incapacitated for work about a month. He kept his men all in line, all at work, until his breath became so short, probably through involvement of the kidneys in disease, that it was so painful to him he gave it up. He remained at home after that, and died about a month after ceasing to work, and yet carried this enormous heart. I have never seen a very large heart in a person in whom it did not begin to grow in early life.

The heart may be hypertrophied in the wall of one of its cavities. The hypertrophy usually found about the heart is that of the walls of the left ventricle. The left ventricle is hypertrophied oftener than any other portion of the heart. You will find, also, hearts that are hypertrophied in all of the cavities; perhaps some such among those that I shall show you at our next meeting; and others, perhaps, that are hypertrophied in the two ventricles; and one or two, I think I have, that are hypertrophied in the right ventricle, the right auricle, and the left ventricle. So that hypertrophy may be single, or it may occupy each one of the walls of the heart cavities.

The causes of hypertrophy are various. The most common cause is the need of more strength in the walls of the cavity that is immediately affected. Obstruction, then, at the aortic opening, as has already been stated to you, is attended by hypertrophy. It is at first over filled, and it has to make up for the loss; but the heart does not seem to know exactly when to stop growing, though it does know when to begin to grow, and it may go on to become diseased. A moderate hypertrophy, then, with obstruction at the aortic opening, may not be regarded as a grave disease. Then, regurgitations will lead to hypertrophy. That the obstruction not requiring increased strength in the walls of a cavity will not produce hypertrophy, you will see in the fact that stenosis of the mitral valve is attended by no change in the left ventricle. If there is regurgitation, then the left ventricle may become hypertrophied. It needs more strength for the work it has to do. But if it is simply an obstruction of the blood coming from the left auricle into the left ventricle, and the left ventricle becomes in the end fairly filled, and does not throw the blood back again into the auricle, then there is never any hypertrophy of the left ventricle. It is only in regurgitation with this lesion that hypertrophy comes. Here, then, is one cause.

Another cause is increased strain upon the heart; an increased demand continued for a long time, attended by a nutritive, non-deteriorated condition of the blood. You see why I make that limitation: because a man with typhoid fever may have his heart beating rapidly and pretty strongly for four weeks continuously, and no hypertrophy follow. But then his blood is deteriorated; all his tissues are, throughout. If by mental or physical excitement his heart should beat this way, at the same rate and for the same length of time, and his blood were in a nourished condition, it would become hypertrophied to a certain extent. Disease that produces increased action of the heart and full action of the heart,

does not, then, give hypertrophy, unless the blood is in good, full, nutritive condition. Occupations that are attended by great mental excitement and by heart beating are dangerous in this respect, producing only hypertrophy without valvular disease. The little tyrants that command on vessels at sea sometimes are very passionate men. I have seen them beat their men about and swear at them as if they belonged to our army in Flanders ; and those men are very apt to get hypertrophy of the heart. They do not observe the rule of scripture, let not the sun go down upon thy wrath. They are wrathful after night. A French physiologist has interested himself in the cardiac condition of the domestic fowl, and he found that where one rooster was to be the husband of ten or twelve hens, he was apt to get hypertrophy of the heart. This may be a warning in regard to sexual indulgence.

Then, again, hypertrophy comes from causes that are not known. We say in general that it is an error of nutrition, but why, we do not know. Persons of quiet temper and of easy life, not subject to particular excitements, and having no valvular disease of the heart, do once in awhile get hypertrophy of the heart; but it is uncommon ; decidedly uncommon.

Now the question comes, how to recognize hypertrophy of the heart. A heart like that one that is passing around, which I told you is hypertrophied, occupies a greater space in the chest than it did when it was of normal size, and what will that do? It will crowd the lung away. The space over which a heart of natural size will practically come in contact with the walls of the chest, or, in other words, not be covered by lung, is about equal to two superficial inches; but when a heart grows, as that has, it must crowd the lung out of position. In a healthy person you can hear the respiratory murmur over the whole præcordial region ; but when you listen to a person who has considerable hypertrophy of the heart you will very likely fail to find the respiratory murmur over the anterior portion of the heart, because the lung has been crowded away. That comes to be, then, one sign for the recognition of it. The same thing, however, occurs when the pericardium is dilated with fluid. The lung then is necessarily crowded away in the same manner.

Another point is, that the region of dullness is increased more or less markedly. The point to which the apex of the heart can be pushed to the left by its hypertrophy is perhaps six inches and a half from the median line. Then you get to about the outer curve, the outer limit of the curve of the chest. It may be pressed backward beyond that, but I do not remember to have measured a heart which extended to the left more than six inches and a half. I have found it six inches a great many times, and five inches and a half a great many times. You can measure it in either one of two ways. Find the apex, and be sure that there is no heart beat beyond that, and you can pretty safely measure up to that point from the median line. But it is always better to make percussion, so that you will be sure of the point to which you should measure. Dullness over the lung upon an enlarged heart is very decided. The line of division between them is pretty clearly cut. Yet, even suppose you get dullness over six inches from the median line, your diagnosis is not yet made. The same thing may happen with pericarditis and an enlarged pericardium. Then, seek for the apex of the heart. If there is marked enlargement of the right side of the heart the apex will be tilted up toward the axilla. It will be, perhaps, as high as the fifth rib, following the curve of the rib upward, or it may not be as high as that. Its direction is upward and outward, and to the left. If it is the left side of the heart exclusively that is hypertrophied, the apex may be situated in the seventh intercostal space, outward, downward and to the left. Of course, it will be in the sixth before it is in the seventh. It is in the intercostal space, of course, that you can most easily feel the impulse of the heart. And then, again, you must make percussion to verify the indications of the apex beat. There is nothing that is likely to trouble you in the attempt at diagnosis but pericarditis. It is true, the heart is sometimes the seat of tumors; and the pericardium becomes enlarged sometimes by air, but that will not give dullness. In general practice, with the exception of the extraordinary cases, that you do not expect to see, these two things will give you the only trouble there will be. Hypertrophy is otherwise easily recognized. There is a point, however, to be borne in mind. I examined a gentleman who had been educated to the profession, but had gone into business, yesterday. He had pleurisy filling the left side of the chest, and his heart was pushed over so that the apex beat was about in the position on the right side that it would naturally occupy on the left, crowded over by this accumulation of fluid in the left side of the chest. Now, a person who has hypertrophy of the heart may have a pleurisy as well as anybody else, and the heart may be displaced in the same way. It may be displaced to the left also. An effusion upon the right side will enroach upon the medias-

tinum sufficiently to crowd the heart over an inch further to the left than it naturally would be. Such a case as that you may mistake for hypertrophy, when it is only a displacement. It will be important to know, then, whether there is any effusion upon the right side of the chest.

Then, again, the history of hypertrophy and of pericarditis will be found different. Hypertrophy is a chronic affection, and a man who has it, and is sent to you for it, will have had, for a good while, some shortness of breath in going up stairs. Then, again, the dullness extends, in pericarditis, as I have already told you, in a direction different from the dullness in hypertrophy. You get a certain degree of dullness, in pericarditis, with copious effusion, on the right side of the sternum, and you get it above the third rib. It is only fluid effusion in the pericardium that does that. The physical signs of hypertrophy, therefore, are pretty clearly made, pretty clearly cut, and you need hardly make any mistake about it.

The rational signs are more obscure. You cannot be sure, by any study of the general symptoms, that you have hypertrophy and nothing else. You can pretty easily determine, from the rational symptoms, that there is heart disease, but exactly what it is, is almost impossible. The usual symptoms of heart disease are to be observed in these patients, that is, a certain degree of shortness of the breath on exertion, frequently a disposition to rest the head on two or three pillows, instead of one, in sleep; a disinclination to sleep upon the right side of the body, not because it gives them pain, but because it disturbs them, it makes them nervous; they feel the heart beat, and that makes them nervous. Palpitation cannot be relied on as a means to distinguish hypertrophy. It is wonderful how much of thumping the heart will have, and the patient be entirely unaware of it in some instances; and it is really surprising how little of real palpitation will give other persons much uneasiness. There is a real palpitation and there is a subjective palpitation. Persons of particular habits will become nervous and feel palpitation when there is only natural action of the heart. It arises alone from their increased sensitiveness or the heightened state of nervous perception. And then, as I said before, a man who has real hypertrophy of the heart, who has been accustomed to hard knocks in life, may pay no attention to it, while it will lift your head half an inch at each beat, when you apply your head to the chest. It knocks like a hammer against the face and ear; and yet, ask him if his heart palpitates? "O no, O no, my heart is good!" But palpitation is not a certain guide to diagnosis. The man that was at the clinic yesterday had no palpitation; that is, nothing that you could feel with the hand. You could feel that the heart was beating, but not with extraordinary force. He had had his disease for a considerable time, and it is to be presumed that the heart had lost some of its energy. But even in persons in whom the disease may be gradually growing there may be decided palpitation, and there may not be, so that you will have to consider what is the cause of the palpitation if you find it.

Shortness of breath is common to almost all the forms of cardiac disease, so that there is nothing particularly distinctive in that.

Then comes the question, what can be done for the relief of these patients? and then, again, as all the diseases, or nearly all the diseases, of the heart, have about the same physical history, their treatment will be substantially the same, so that I will say what is to be said about that further on.

There is another condition of the heart walls that deserves particular attention. I say particular; it is not nearly so common as hypertrophy with dilatation. It is dilatation alone. And this brings me to the question, what produces dilatation of the heart, whether it occurs with hypertrophy or singly? The answer to this question, I think, has been given by Niemeyer: dilatation of the heart by a reflux of blood into it, which blood has just been thrown out of a cavity. For example, the blood is thrown into the aorta, there is a reflowing, a reflux of it into the ventricle; perhaps one-half of it that was thrown out comes back again, and this is in the period of non-resistance of the heart; its muscle is all relaxed, flabby. If it were to come during contraction there would be resistance to enlargement, but the muscle is, so to speak, dead at the moment; it is in the period of repose that this reflux takes place. It stretches it, together with the blood flowing in from the auricle. It is compelled to contain more than it was made to contain, and the result is a moderate dilatation, and this continued seventy two times a minute, for days, and weeks, and months, will produce an effect. One occurrence, probably, would not be felt, but a repetition is what produces the dilatation. Well, this dilatation, then, is caused by an unnatural flow of blood into the ventricle, and the heart feeling its contents, naturally acts with more than ordinary force, so that hypertrophy and dilatation often go together, step by step.

Communications.

PNEUMONIA.

BY HIRAM CORSON, M.D.,
Of Norristown, Pa.

(*Continued from page* 176.)

Professor J. Russell Reynolds, in the introduction to his "System of Medicine," vol. 1, page 30, after speaking most disparagingly of the treatment of "a few years ago," seems to have been somewhat conscious of the danger of his teaching, and therefore added: "If we can, by bleeding, and by it alone, save the eyesight which may be threatened by iritis, or if we can, by depletion, save a life endangered by laryngitis, we are quite satisfied in adopting that measure, though it may entail some injurious consequences. It would, however, be as unkind as it would be unphilosophical, to relieve the pain of a simple pleurisy by abstracting blood in such amount as should damage the individual in after years, when equal relief might be obtained by *poultices* and *patience*." One meaning of the word disingenuous, given by Webster, is, "meanly artful," and with that meaning in my mind, I say the above statement is disingenuous; for no advocate of depletion, in those cases, would be likely to carry it so far as to injure a patient permanently. I have never seen a man who had recovered from a laryngitis or pleurisy, where venesection, or cups, or leeches had been used, who showed any evidence of injury from the depletion. And I do not believe Dr. Reynolds can point to such a case, nor that any physician in Philadelphia has ever seen such a case. Let the opponents of depletion by venesection, if they cannot show us a case of that kind, point us to the disease or injury likely to be caused by the abstraction of blood sufficient (with the aid of the means in vogue) to cure these diseases, before the treatment by digitalis, verat. virid. and aconite took their place. What injury would now be likely to follow such loss of blood? None; absolutely none. I have bled freely, in hundreds and hundreds of cases, and never have seen any bad results follow after the recovery from the acute affection which it had aided to relieve. It is easy, perhaps quite pleasant, for Dr. Reynolds to write about means of cure of which he likely knows almost nothing; but while it is fun for him it is death to the patients of those readers of his volumes who are looking for a guide to practice in the cases of which he speaks. And what is it that he recommends in the place of depletion, in inflammations of the pleura, the lungs, iritis, and laryngitis? Poultices and patience!

That reminds me of a physician whom I knew very well, and who, when sent for to a rheumatic patient, always advised, "red flannel and patience and rest in bed;" his neighborhood was filled with cripples—legs and arms, and fingers contracted and stiff and useless for years. In Dr. Reynold's region I would expect to find many blind, and others voiceless, or dead. Just here it occurs to me to put against the author of the "System of Medicine"—whom I have noticed here only because he is the exponent of the new practice of poultices, patience and a few poisons deemed very hazardous by the bulk of the profession—the experience of Professor Gross, of Philadelphia, on this very subject of inflammation of the tissues of the eye. In a discussion which took place at one of the meetings of the Medical Society of the State of Pennsylvania, on the efficacy of venesection in acute inflammations of the various organs of the body, Dr. Gross gave the following illustration of the effect produced by that kind of depletion, contrasting it with the effects produced by veratria and aconite: he said, "Suppose the conjunctiva to be inflamed, so that the small vessels are distended with blood, and the physician should bleed him to syncope; the membrane would become pale, and the vessels would be relieved; but not so if, by the almost poisonous use of verat., you should reduce the pulse to half its usual number of beats per minute." I do not pretend to give his words; the above conveys their exact meaning. What a striking illustration! and how true! And had it not been that I wished to give Prof. Gross the credit of it, I would, in my last article, have stated my views in relation to the mode of relief procured by venesection, in pneumonia and pleurisy and other inflammations; as it acts on the eye, it acts on the capillaries and small vessels everywhere. When congestion has set in, on the lung, a good bleeding, that makes a decided impression on the system, takes away the force of the circulation which is pressing the blood into the small vessels and thus blocking up or squeezing the sides of the air cells so that no air can get into them, thus relieving the congestion, the first step in the diseased process produced by the primary irritation. So distended are these vessels before the blood is drawn, that the blood in the capillaries of the lungs is oozing through the mucus membrane and being coughed up as blood and rust-colored sputa, but after the bleeding there is almost no expectoration for hours, the vessels, like the vessels in the eye spoken of by Dr.

Gross, are relieved, the extra amount of blood has been drawn away, or is so relieved from the pressure behind that it is no longer driven into them, and opportunity is allowed them to relieve themselves, and the air to be again permitted to reach the cells.

I have often seen immediate relief thus produced; it was so in Canarra's case; from the time of the bleeding and cupping in the forenoon of one day until the evening of the next day he was comfortable, breathed easily, and if he had had a good nurse, would likely not have needed more treatment of the depleting kind. From that time, too, until the revival of the inflammation, there was but little expectoration of the viscous sputa. Every close observer must have noticed the great diminution of the characteristic exudation after a free bleeding for many hours. Although I seem to be getting entirely away from Dr. Reynolds, I feel as though this is a good place to speak of a change often made by the new lights—or, to speak more respectfully, the opponents of bloodletting—namely, that "the more you bleed the more inflammatory the blood becomes;" the increase of fibrin, the "buffy coat," on the top of the crassamentum, being the index to the inflammatory condition. In my experience this is not true. Many years ago this objection was urged against it, by a friend who was, in a friendly, private way, as an "eclectic," wanting me to abandon it. From that time I was careful to observe the effects of bloodletting on the crassamentum. And here are the facts, observed over and over again:—

Suppose a man, commencing to be affected by pneumonia, to be bled when the congestion has advanced for a few hours, but has not yet caused inflammation to any considerable degree. There is yet not much increase of frequency of the pulse; but little if any thirst; not much pain or cough. The blood drawn does not show the buffy coat at all, or, at most, to a very slight extent; and if the bleeding have been a free or copious one, the progress of the congestion will be arrested, it will extend no further, and that existing will be soon removed and the patient well. But suppose that the bleeding be an inefficient one, not sufficient to make a decided impression on the system; in that case the inflammation will progress almost as though nothing had been done, and before the return of the doctor on the following day will have a thick, buffy coat. There was, at the time of the first bleeding, but the very commencement of inflammation in the part, and the blood had not been affected by it. Might I not say, was not yet poisoned by the inflammation? And this suggests another thought: *The change in the blood* evidently *comes from or is the effect of the inflammation on the system.* Not the disturbance of the system and the local inflammation, from an inscrutable something which, in a state of health, has insinuated itself into the blood. This view of the case will be considered hereafter. The first bleeding, when the inflammation had but just commenced, showed no fibrin; the second, a strong, firm coat; and if this last one was sufficient to arrest the extension of the disease, the blood drawn next day would show a very diminished amount of fibrin. You may bleed a healthy man to day, and again to morrow, and, my word for it, there will be no increase of fibrin found in the blood drawn the second time. I may appear very tedious, but this point is one much dwelt on by the opponents of the lancet; indeed, it was almost the only stock in trade of the Thompsonians and Eclectics, in their early war against venesection by the "regulars," as they called them, and if bleeding were dangerous we should here have a good guide. The diminution of the fibrin on the top of the black clot of blood swimming in the serum would suggest caution; but it is not a dangerous remedy when used to relieve acute inflammations. It is infinitely less dangerous in the hands of the common practitioner than is digitalis, or aconite, or veratria, as I hope yet to prove.

But let us return to Dr. Reynolds, one of the leaders of the blood-poison, poultice and patience schools. He continues, "We still find it written, if these conditions are found, a hard, full, strong, frequent pulse, with great heat of skin, no prostration, then bleeding, antiphlogistics and the like, must be employed. But, as a matter of fact, we do no not find these cases, and the more common *on dit* of medical practice is to the effect that, as the inflammation seemed extending, the quantity of wine has been doubled, the supplies of beef-tea increased, and bark and ammonia given more frequently." And he emphatically denies that the *type* of disease in England has altered. Without following him through all his praise of the present poultice and patience, and veratria and aconite practice, and denunciation of "the practice of a few years ago," I will pass to his summing up: he says, "If the general condition be one of weakness, it matters not that the brain, the heart, or the lungs may be in a state of so-called inflammation; *the weakness is the one thing that demands immediate treatment*, and to neglect *its* treatment is to run the risk of sacrificing the patient to a theory of a compound state, even

now but imperfectly understood." (The italics are mine.)

In the above extract we have a synopsis of the belief, or theory and practice, of Dr. Reynolds and the opponents of depletion in this country. It matters not that "the pulse is full, hard, strong and frequent, with great heat of skin and no prostration;" he and his disciples cannot see them. They see only great weakness, and in that a demand for more wine, more beef tea, more bark and ammonia. My patient's case was a typical one, to them; a case in which they would have seen only weakness, a weakness calling for wine, beef-tea, bark and ammonia. The "weakness" which he exhibited being the one thing that, in their eyes, demanded immediate treatment.

In regard to "the weakness being the one thing that demands immediate treatment," and to his other declaration that it is "the starting point, the essential element in therapeutics," the American editor of the work, Dr. Henry Hartshorne, one of the most learned and accomplished physicians of the city of Philadelphia, when, I am proud to say, the profession is full of men the equals in intelligence and skill of those in any country, thus discourses: "Few, if any pathologists will hesitate to admit that a difference, often momentous, exists between the *exhaustion* of a system weakened by the continuance for some time of severe disease, and that *oppressive* debility with which the most robust person may be temporarily affected under the influence of an acute malady, such as pneumonia, meningitis, or croup." Had I regarded the "oppressive debility" of the boy Canarra, as Dr. Reynolds and his followers would have regarded it, as an exhaustion, and given the bark and wine, the beef tea and ammonia, a poultice all over him would not have saved him.

I made the declaration in my first paper, that before the advent of the new treatment by the poisons, veratria, digitalis and aconite, and by overloading the stomach with food, the physicians of thirty years ago rarely lost a patient from pneumonia, and that at the present time it is so fatal that it is one of the most dreaded of our diseases; and yet with the blood-poison believers the very contrary is considered to be the truth. Only last week I met a gentleman, a very intelligent man, having a large practice, but who has not practiced more than fifteen years, perhaps, and one reason that he gave for not bleeding in pneumonia, and even, too, in other diseases, was that "when physicians used to bleed and cup in pneumonia, it was much more fatal than it is now. Poor fellow! I pitied him, and trembled, in view of the danger to those who should hereafter employ him in that disease. He had gotten this idea from Dr. Reynolds and others of that kind. In support of my declaration that it is much more fatal now than before the poison treatment came into fashion, under the name of antagonistic treatment, allow me to quote again from Dr. Hartshorne's comments, on page 32: "The mortality of pneumonia in Philadelphia has, for some reason, certainly increased; not in the hospitals, where the average character of the patients has always made them unfavorable subjects for depletion, but in private practice."

It is not too bold an assertion, indeed, for one who, without partisanship, maintains his conviction of the occasional importance of venesection and local depletion as remedies, that, while uncomplicated pneumonia, under moderate depletory treatment, was, thirty years ago, rarely fatal outside of hospitals, and not frequently so within them, *the indiscriminately stimulating method now often applied to all classes of cases has increased very considerably the fatality of this and other inflammatory diseases in private practice.*" (Italics mine.) What a commentary on the boasted skill of those who rely, for the cure of pneumonia, on digitalis and carb. ammonia, or veratria and whisky, or aconite and poultices and patience. How ashamed the teachers of medicine in Philadelphia, lecturing to large classes of young men who know nothing of the great value of depletion as practiced in former days, should be, to be denouncing it now, and teaching them that it was more fatal than their present treatment! What will their pupils think of such teaching when they read Dr. Hartshorne's approval of that which they have been taught to regard with horror, and his declaration of the fatality of that treatment which they have been urged to accept as the best? Dr. Hartshorne has been a close observer, has practiced in and out of hospitals for more than a quarter of a century, and knows whereof he affirms, has seen the life-saving power of depletion, and the fatal results of the stimulant and stuffing practice, founded on nothing but the *apparent* weakness so invariably present in real pneumonia. I say *real* pneumonia, because some of these new lights seem to regard all slight bronchial affections as pneumonia, and boast of scores of cures, when they have never had a single case of inflammation of the lung. If they do have a real case it is almost certain to prove fatal; and then they call it typhoid pneumonia; they tell what a *fearful* case it was; "how weak, how prostrate; it was impossible to keep him up,

with all the whisky we could get down him; he was greatly oppressed, and as a proof of the severity of the case, he only lived three days after we began his treatment, though, to sustain the action of the heart, we gave him twenty drops of tinct. digitalis every two hours." They might have added to this, "and sent antagonistic remedies through the blood to neutralize the poison which produced the disease." It does not occur to them that they might turn their attention to the condition of the diseased lung. It is strange that under such treatment the patient should have lived so long as even the short time of three days.

I have repeatedly seen in the newspapers announcements of the death of persons from pneumonia, headed "suddenly;" and suddenly, indeed, many of the deaths are, from such poisons as digitalis, veratria and aconite, when given, as they often are, in large doses. It would be a rare thing for a person to die of pneumonia in three or four days, if let alone. I have used the term poisons in speaking of three articles in common use by the opponents of depletion, and have used that term for a purpose, which may be seen hereafter. It pains me to see how very fearful our young physicians are of depletion by taking blood. They are really conscientious in their refusal to follow a practice which they have heard denounced in strong terms. Even Dr. Pepper, who tells the students that cups are useful; and even says that "if inflammatory reaction is very great, with intense throbbing pain in the head, great dyspnœa, etc., venesection produces effects with more certainty than local bleeding," hedges its use in ordinary cases with so many restrictions, that a graduate fresh from his teaching would use such depletion with fear and trembling. But I am obliged to the Professor for the declaration of its usefulness. I have no fear to use it in any case, in the very young or very old, as well as in the strong adult. There is no remedy more readily adapted to the varied conditions or degrees of inflammation. While writing the preceding page of this paper, I received from my friend, Doctor Traill Green, a practitioner of more than forty years' experience, and well known all over our country, the following letter, which I take the liberty to insert here, as evidence that the remedy which we recommend may be used on weak people with as much efficacy as on strong ones, and that advanced age is no bar to its use.

"I am glad that you are calling the readers of the Med. and Surg. Reporter back to the use of the lancet. In the days of our pupilage and early practice the medical practitioner always kept the lancet near at hand. I wonder whether our young doctors know how to use that instrument. And the professional bleeder and leecher has disappeared. Then where shall help be found for those who are ill of inflammatory diseases? Nothing has as yet been found that can take the place of bloodletting in such affections. The speedy relief of pain and heat is so marked that patients themselves notice the change. I remember an attack of pleuro-pneumonia which I had when eighteen years of age, and the permanent relief which followed two free venesections made within twelve hours. The recollection of this relief in my own case always made me prompt in the use of the lancet after I entered the medical profession. I remember a call during the night, many years ago, to an aged woman who was suffering as I did at eighteen years of age. She had passed, or approached closely her threescore and tenth year, and Shakspeare's description of old age applied to her remarkably well: 'Sans teeth, sans eyes,' and she was very thin in flesh. It was a case which called for prompt action, and, of course, the question came up, shall I bleed her? Will it be proper to abstract blood from one so advanced in years and apparently so feeble? It was not convenient to call a consultation, and I had to decide alone. I felt it was safer to bleed her than to allow an inflammatory affection to run its course. I therefore opened a vein and allowed the blood to flow until the pain was relieved and the force of the pulse was reduced. When I made a visit the following day, I found my patient in a comfortable condition, and further treatment was unnecessary. I have always believed that I arrested the inflammatory condition of the lung at once. I would not hesitate to pursue the same course in treatment of a similar attack, in one advanced in life, at the commencement of the disease. I think fewer fatal cases of pneumonia would occur in the aged if venesection were generally practiced."

Such is the testimony of a practitioner second to no man, in city or country, and I wish your readers to observe what he says about arresting the progress of the disease. A single bleeding cut it short at once in his aged patient, and in twelve hours his own affection was relieved; and in neither of these cases were any "antagonistic remedies" sent through the blood to grapple with, and destroy the poison playing havoc there. How silly is this talk of "keeping up the strength until the disease has time to run its course."

What is its course? Congestion, inflammatory engorgement, purulent infiltration, death, or, at least, lingering, partial recovery. The subject grows before me. What part I shall consider in my next, I know not.

Hospital Reports.

ST. MARY'S HOSPITAL, PHILADELPHIA —EYE AND EAR DEPARTMENT

CLINIC OF H. AUGUSTUS WILSON, M.D.

A Case of Convergent Strabismus, or Squint.

Joseph S., aged twelve, is a school boy, and his cause of complaint is very apparent. The left eye, as you see, turns inward, and it will be interesting to determine the degree of convergence. By using this little instrument, called a strabismometer, which is merely an arc of ivory fitting the lower lid, and graded from the centre each way, in lines and half lines, we can readily learn the exact amount of the deviation. I now apply the instrument to his left eye and direct him to fix with the right on a point directly in front of him. You can all see that the pupil turns inward two lines from the centre of the arc, and I will therefore record the degree of convergence as two lines. By means of prisms you can find the deviation just as accurately, but when there is defective vision I always prefer the strabismometer.

It is not indispensably necessary that the convergence should always be measured, but for the sake of accuracy of record I generally resort to it.

We must next determine the cause of the trouble, for on this must depend the question of treatment. The immediate cause is, of course, a preponderance of power in favor of the internal rectus over the external. Now this might be due to paralysis of the sixth nerve supplying the external rectus, to spasmodic contraction, or simply to over action of the internal rectus. The first we can readily exclude by noting that the patient can follow my finger as I pass it from him, outward, and to the left. If it were due to clonic spasm of the internal rectus, as by the irritation of a growth in contact with the nerve, it would not be of so long standing as the history indicates; for such growths soon become of sufficient size to produce pressure, and in that case there would be paralysis of, not only the internal rectus, but also the superior and inferior recti, the inferior oblique, and levator palpebræ superioris, all of which muscles are supplied by the third nerve. There would also be dilatation of the pupil.

The case then reduces itself to simple over action of the internal rectus, and it is said that post-mortem examinations, made in cases where there has been strabismus, show a higher coloration of the muscles and some hypertrophy, due to this over action.

But what has caused the over action?

Anything which makes the vision of one eye defective, such as a corneal opacity, or a defect of the retina, or anything that will cause the image in one eye to be imperfect, may cause the mind involuntarily to turn that eye out of the way, to avoid confusion. Or, what is by far the most common cause, hypermetropia, or far sight, either in one eye or in both. Donders says that hypermetropia is present in seventy-five per cent. of all cases, while in fifteen cases that I have operated upon hypermetropia was present in every instance.

The eyes in their normal condition should act in strict unison, the images produced on their retinæ occupying exactly corresponding positions, so that their united effect is to produce a single impression on the brain, like the solitary eye of the ancient Cyclops, which occupied a position in the centre of his forehead.

Now, by means of the ophthalmoscope I have determined that this patient has a patch of choroidal atrophy in the neighborhood of the yellow spot of Sœmering.

This, very probably, forms one element in the cause; but we will now test his vision, and determine whether an error of accommodation does not also exist, either of which conditions, if present, would be sufficient to account for the deformity.

This test must be made while the eyes are under the influence of a mydriatic, in order to determine the refraction independently of the changes in the accommodation produced by the contraction of the ciliary muscle.

I find, as you see that at the distance of fifteen feet he can read number forty of the test types with his right eye, while with his left he can only read number seventy.

This I indicate by the fraction $\frac{15}{XL}$ the numerator being the distance at which he can see it, while the denominator indicates the distance at which it should be seen. That is, with the right eye he reads at fifteen feet what the normal eye should read at forty feet, while with the left at the same distance he can only read the large letters which the normal eye should read at seventy feet $\left(\frac{15}{LXX}\right)$.

The left, you see, then, is only a little more than half as good an optical instrument as the right.

Let us now see how this causes the left eye to turn inward. The third pair of nerves which supplies the ciliary muscles with the power of rendering the crystalline lens more convex, also supplies the internal recti muscles with their power of contraction; while their opponents, the external recti, are supplied by an entirely separate pair, the sixth.

Hence in the condition of hypermetropia it often happens that the child who is subject to this defect will learn to give an increased amount of innervation to the third pair, and thus the internal prevail over the external recti, and convergent squint is produced. But this is not all; if the eyes are turned in beyond the normal degree, of course, the images cannot fall on corresponding spots, and the mind, to avoid the confusion which would arise from dealing with two images not equally distinct, soon learns to fix with the more perfect eye in such a manner that the image will fall on the most sensitive spot of the retina, the macula lutea, and to disregard the impression

made upon the retina of the other eye; choosing, as it were, by a process of "natural selection," the best eye as its servant, and neglecting the other until it becomes almost entirely useless as an organ of sight. I could cite you many cases in which children have in this way so thoroughly lost the use of an eye by this gradual, but certain, process that they would scarcely miss it were it enucleated, and still to all external appearances the eye is as good as the other. After a time this eye, from disuse, becomes amblyopic and past redemption. All this could have been prevented by the use of properly adjusted glasses, which would have relieved the eye of the over strain dependent upon ametropia. But in this case, which is one of hundreds, such a precaution was never taken, and he is sent to me for relief from the cosmetic defect which is so conspicuous

Few persons have such peculiar taste as to admire cross eyes. The facetious will joke, the superstitious will dread, and the truly polite will pity and appear not to notice it; but however it may strike the world at large, the subject is constantly reminded of the existence of the deformity.

The frequent occurrence of strabismus among school children has led to the idea among the laity that it is the result of imitation alone; and this will be given as the cause of the squinting, in nine cases out of ten.

But it has been demonstrated by such men as Donders that the true explanation lies in hypermetropia, at least three-fourths of the cases being due to this cause.

It is not, as a rule, until the child is sent to school, or acquires a taste for close work at home, that this defect shows itself. The eye is congenitally malformed, being too short in its antero-posterior diameter, and in the effort to overcome this defect the unfortunate subject acquires this ugly squint.

Of the fact that defects of vision are congenital you have all doubtless seen many examples; and where this defect takes the form of hypermetropia strabismus is frequently found as a family characteristic, particularly when the children of the family are inclined to read a great deal.

I have now in mind a family of six, all of whom have hypermetropia, and five have strabismus convergens. They furnish a beautiful series of cases (speaking from a scientific and not from a cosmetic point of view), illustrating as they do the various stages of the defect. The father, who is a teacher by profession, has a high degree of hypermetropia, while the mother has very marked convergence, and one of her eyes is almost entirely useless.

The oldest son, a young man of about nineteen, has passed through the usual experience of such patients. His degree of convergence was very great; his left eye became amblyopic; and though I operated on him last June with a very good result, as far as the strabismus is concerned, he will have to pay the penalty of his parents' neglect by carrying through life a useless eye.

The second child, a little girl of thirteen, presents a similar condition not quite so far advanced. In her case an operation was performed by Dr. R. J. Levis, on both eyes, giving an excellent result, the amblyopia not having advanced so far; but still, in her case even, there is a decided advantage in favor of the right eye, which, had it been neglected a few years longer, would doubtless have shown a similar result to that of the son.

In the other children, who are six and eight years of age, respectively, an operation was found unnecessary, the adjustment of proper glasses being sufficient, as the cast, though obvious, was not yet firmly fixed, and, particularly in the younger one, being very slight.

But, to return to the case in hand, there being no contra-indication, and the patient being now throughly anæsthetized, I shall operate.

The instruments needed are a stop speculum, to separate the lids, two pairs of toothed forceps, a blunt-pointed hook and a pair of scissors.

The lids now being held open by the speculum, I evert the eye by means of one pair of forceps while with the other I seize the conjunctiva over the attachment of the internal rectus, and pinching up a small fold, clip it through with the scissors. Through this opening I grasp the tendon with a pair of forceps, then the hook is passed beneath it, and by means of the scissors it is cut off close to the ocular insertion.

Two precautions are necessary; first, to avoid passing beyond the capsule of Tennon, which, if cut, would allow the muscles to recede too far and thus cause an outward squint quite as bad as the first. This, however, with ordinary care, need never occur.

The other point to be particularly guarded against is leaving any of the fibres uncut. To avoid this I make, as you see, repeated efforts with the hook, passing it through from above downward and from below upward and outward, until I am assured that complete division is effected, when the operation is complete.

The wound in the conjunctiva may be stitched, but this is not at all necessary, nor need any dressing be applied.

If there should be exuberant granulations at the point of incision in the conjunctiva they must be clipped off.

The external rectus, by its contraction, draws the eye into its proper position, and in a few days adhesion will take place between the cut end of the tendon and the ball, at a point further back.

But one point I wish to impress on your minds, and that is, the importance of insisting on the constant and continued use of such convex or cylindrical glasses as will correct the ametropic condition which has been instrumental in producing the defect.

The operation for strabismus at one time fell into great disrepute among both surgeons and patients, on account of the frequent recurrence of the defect because this precaution had not been taken. Now, however, since the subject of accommodation and refraction is so well understood, if care has been taken to divide every filament of the tendon, and proper glasses are adjusted and worn, we can confidently expect a good result.

Note.—One month later the patient presented himself at the clinic with no discernible deviation, and no traces of the operation were apparent, except upon close, critical examination, when the cicatrix in the conjunctiva could be seen.

Medical Societies.

NATIONAL ASSOCIATION FOR THE PROTECTION OF THE INSANE.

A conference of this Association was held February 12th, in Boston Hon. S. E. Sewall presided.

General Banks spoke in favor of a more intelligent classification of the insane, which shall separate the criminal and the epileptic insane from patients suffering from the ordinary forms of insanity, and place the recent insane in proper hospitals for active treatment, while the chronic and harmless insane should be under more homelike and economical surroundings.

Dr. Nathan Allen, of Lowell, as an expert, made some practical remarks on the nature of insanity and its causes. In looking for the causes he said: You will find that a leading one is loss of health. As means are found to prevent disease, insanity will be prevented. Another cause is intemperance, but he was convinced that, except in extreme cases, inebriates should never go to an insane asylum. The other causes are numerous and complex. The great thing to be done is to remove the causes, and this will in time be accomplished. These evils, he believed, could be largely remedied by legislation. The remedy will come with the knowledge, which is sure to come sooner or later.

A paper by Dr. A. Reynolds, of the Iowa Hospital, on the subject of the classification of the insane, was next read, in the absence of the author, by Dr. Fisher. The main point of the argument was the separation, so far as it is practicable, of the acute from the chronic insane, by providing small hospitals for the former, and larger and cheaper buildings for the latter, with separate hospitals for the epileptic, inebriate, and criminally insane. He does not believe it safe or proper to discard the mechanical restraints, but their use should be reduced to the minimum and be under the direction of the medical officers. He agrees with many other advanced students of insanity, that there should be some State supervision of the insane, believing that it would be desirable if some uniform system could be adopted. He also believes that every Board of Trustees should have at least one woman as a member, and that every hospital where female patients are treated should have a female physician.

Dr. J. M. Kenniston, of Cambridgeport, next spoke on the subject of preventive medicines. He said that the present National, State, and local Boards of Health are all engaged in the work of promoting the health of the people, by removing whatever tends to cause disease. Insanity is not a crime or a misfortune alone. It is a disease, and as such it must be considered and treated. Each individual case must be studied carefully and treated as scientifically and conscientiously as a case of diphtheria would be treated. Intemperance, spiritualism, morbid religious excitement, thoughtless and mercenary marriages, and sensational literature were mentioned as prolific causes of insanity which should be investigated and remedied.

A paper written by Dr. Walter Channing, of this city, was next read, on the classification of the insane, with special reference to insane criminals and inebriates. It was mainly a discussion of the present arrangements of the asylums of this State and their needs. On the question of classification generally he declared that methods which will take away direct and daily medical inspection should not be considered. Insanity, he said, is a disease. The disease is to be treated, and, if not cured, ameliorated. The physician's profession is to do this, and as a matter of necessity he is driven to use various moral means, which with the insane means to a considerable extent tenderness, sympathy and encouragement. Because the disease is often incurable it is none the less a disease, and it needs unvarying care and treatment. Its subject must be protected from the stern and rigid economy that the public obliges the State to exercise. He commended the Connecticut system of classification. In general the plan contemplates receiving and treating all acute and all turbulent cases in the hospital proper. From time to time, the quiet, chronic patients will be transferred to new buildings at a short distance from the Central Hospital, where good custodial care can be maintained at less expense. There is also an annex in the rear of the main building for the treatment of insane criminals. Here in Connecticut are united the Superintendent's plan, the Willard plan, the cottage plan, and the separate criminal asylum plan, all within the limits of one moderate-sized farm.

Dr. Channing pronounced as the grand mistake of American insane hospital management, that we have gone on erecting one building after another without sufficient regard to the classes of persons who were to use them.

Dr. Ira Russell, of Winchendon, alluded to the importance of the education of physicians in this special direction, observing that few physicians, even at the present day, give much attention to mental diseases, and then Dr. Edward Cole, of the McLean Asylum, read an important paper on the causation of insanity.

Dr. Cole said that the starting point of all efforts at prevention is the ascertaining and classification of the causes of insanity. He considered the system adopted in most asylum reports as utterly inadequate, and as the value of results depends upon adequate expression in statistical tables, a more perfect tabulation is much needed. In the causation of insanity many influences contribute, and as in other abnormal or diseased conditions, a truly scientific knowledge of mental disease is first required before its prevention can be effectively dealt with. This is not alone for the specialist in lunacy practice. But for the larger purpose of prevention, all medical practitioners should be well instructed in a knowledge of lunacy and its causation. The influences producing insanity were enumerated as hereditary, neglect of sanitary laws, immorality, intemperance, defective education, lack of moral training, and all that tends to the development of a healthy constitution and sound body, he said, was of importance in the prevention of insanity.

Dr. Wilbur, of Syracuse, sent a letter containing valuable suggestions and statistics, which was read. He writes that at least 60,000 insane per-

sons are to be found within the territory of the United States. Ninety per cent. of these are doubtless incurably insane, and probably an equal percentage is supported at the public charge. The ratio of the insane to the general population is a constantly increasing one. They are scattered through the several States and Territories, under varying laws and differing policies, to be cured or helped. They must be treated by every means or agency that medical science in its latest development can furnish for their relief. In looking for the predisposing causes of insanity and the best methods of the treatment of the insane, we must, he writes, invoke the aid of the general practitioner of medicine and the medical specialist, and try to enlist them in contributing studies in this direction. Nor should we forget those engaged in the work of education. Their aid is especially needed in various ways. Already the influence of excessive study has been quoted as a producer of insanity. Dr. Wilbur is inclined to think that too much stress has been put on this as a cause. It is not, he thinks, so much the amount of study as the modes and subjects of study, that are at fault. In his judgment, reviewing the question from an educational standpoint, there is less danger from crowding the intellects of pupils than from neglecting their moral culture. Many years ago there was published in a series entitled "Small Books on Great Subjects," an essay by Barlow, on "Man's Power Over Himself to Control Insanity." The main thought of this essay was that a habit of self control from youth upward, and a mind well poised, had much to do in securing immunity from this malady. A brief discussion followed, and the conference adjourned at a late hour.

Tinctura Rusci.

A correspondent, says the *Am. Jour. Pharm.*, inquires for a formula for this tincture, which is recommended for ringworm, by Prof. Kaposi, in Hebra's work on skin diseases.

Of the genus Ruscus, which is classed with the smilaceæ or liliaceæ, three species have been employed medicinally, all of which are indigenous to Southern Europe, one R. aculeatus, *Lin.*, or butcher's broom, being also found in England. The rhizome, known as *radix rusci* or *brusci*, possesses aperient and diuretic properties, and was formerly much used in visceral diseases. This is doubtless the species employed for the above tincture, but we have been unable to find a formula in old and recent works, though several give directions for decoctions. Since the dose was from ten to thirty grains in powder, the tincture is, perhaps, best made of twenty parts of the powdered drug, exhausted with sufficient dilute alcohol to obtain one hundred parts. The taste is disagreeable, sweetish and bitter.

The other two species referred to are Ruscus hypophyllum and R. hypoglossum, *Lin.*, the former of which was known as *laurus alexandrina*, the latter as *bislingua*, *uvularia* and *laurus alexandrina angustifolia*. The root and evergreen leaves were employed in diseases of the uterus and bladder.

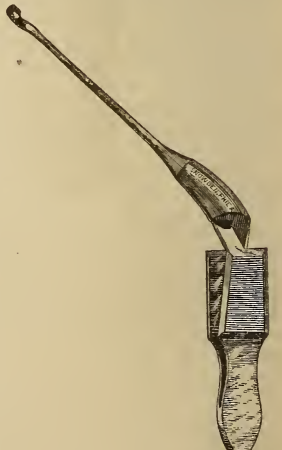
Artificial Membranæ Tympani.

We make the following extract from Dr. Laurence Turnbull's work on *Defective Hearing*, just published. It has general interest to all practitioners:—

Owing to a certain number of properly selected cases having been benefited by the use of the artificial membrana tympani, unprincipled men have sent advertisements all over the country, stating that they are applicable to all forms of deafness, and thus receiving the price in advance, the poor victims find, when too late, that they are not of the slightest use to them.

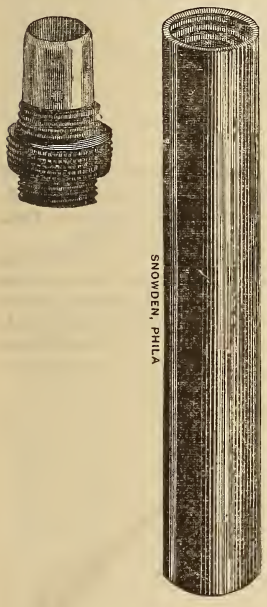
When there is still a portion of the membrana tympani remaining an artificial membrane can be employed. When there is much pus or mucus in the auditory canal it must be first removed. In the class of cases where there is no membrane to be seen, and nothing remains but the promontory, and perhaps the stapes in position, we have found nothing so useful as the ball or an elongated cone of boracic acid cotton attached to a fine thread and passed down to the proper place by the forceps of Professor Gruber (see Fig. 1), where the membrane should be, and the thread placed behind the ear. Two interesting patients now under my care employ this form of apparatus; one is a pupil of our Central High School, and the other is a draughtsman; the former finds ordinary cotton not suitable, and prefers the antiseptic cotton as a long hollow roll on a bodkin; he introduces the cotton on the bodkin, and then withdraws, leaving the cotton in position; and by whistling he determines if it gives the proper note; with the cotton in position he is able to keep his place in his class, and without it he is utterly unable to hear only the loudest voice spoken into his ear, his opposite ear being entirely lost to him, from

Fig. 1.



malignant scarlet fever. No form being appli cable to all cases, each case must be fitted, like eye-glasses. Another class will bear the use of the thin rubber cloth and metal stem ; if pressure is required to bring the little bones in place, it is attached to a fine silver or gold wire. If there are granulations they must be removed by touching them with sulphate of copper if the bone is affected ; if scrofulous, equal parts of tincture of iodine and glycerine, or tincture of iron in the place of the iodine. If the granulations are polypoid in character, they are to be removed by the wire snare or forceps. For the treatment of the remains of polypi or granular growths, employ warmed spirits of wine, to be allowed to remain ten or fifteen minutes daily. If hypertrophic or vascular, employ chromic acid, glacial acetic acid, or chloro acetic acid, or if these fail, galvanic cautery. If syphilitic, nothing is so useful as iodoform in very fine powder, dusted on iodoform cotton. If the granulations are from phthisis, employ tannic acid and carbolic acid combined in equal parts. In plugging the meatus, we find it convenient to moisten the lower portion of the cotton-plug with a small portion of yellow oxide of mercury ointment, one grain to the drachm of vaseline, as the cotton becomes dry, and if not so anointed will adhere to the meatus or auditory canal.

Fig. 2.



By the aid of the punch of Professor Gruber (see Fig. 2), the proper material can be cut so as to fit the ear as an artificial membrane, and can be introduced by the use of his little forceps (Fig. No. 1), with ease and comfort to the patient, and each individual case can be fitted to the best advantage.

The Bougie as a Tampon.

Dr. W. T. Carter describes, in the Louisville *Med. News*, his plan of using a bougie as a tampon. He instances a case where he was summoned to uterine hemorrhage: As I arrived she exclaimed, "Doctor, my sickness has come on me and I am dying—I am flooding to death." Her female friends had her propped up in bed, and were busily fanning and dashing water in her face, to revive her, for she often swooned. Her blanched, bloodless face and feeble pulse told all too plainly that her fears were well grounded. As quickly as possible she was placed in the recumbent position and the usual examination made. The os and cervix were hard and considerably elongated. The uterus was so low, in fact, that by pressing upon the hypogastrium with the left hand I easily compressed the os tincæ between the index finger and thumb of the right hand, thus effectually checking the hemorrhage for the time being. If a strong rubber ring had been convenient I think I could have put it in the cervix, and by closing the canal it would probably have controlled the discharge until there was danger of its producing strangulation. So great was her exhaustion and depression that I did not feel justified in removing my hand until I could replace it by something equally as efficient. My fingers grew tired and were relaxing, from fatigue. In this crisis I took from my pocket a bougie (size No. 8), and had a thread passed through it about a quarter of an inch from its point. With this thread a conical pellet of cotton was securely fastened around the bougie where it was pierced. It was then passed to the right hand, the point carefully introduced and gently forced up until the shoulder of cotton was securely impacted in the os, entirely preventing any further loss of blood. Once during the succeeding night uterine pains coming on she removed the bougie, but the hemorrhage appearing she successfuly readjusted it again. To keep the instrument in position the lower end should be attached to the thigh with a small tape or ribbon.

The Treatment of Fatty Heart.

In a lecture in the Buffalo *Medical Journal*, Jan., Dr. H. R. Hopkins says, on this subject:—

What shall we say concerning the treatment of fatty heart? In most cases your attention will be engaged in the management of the secondary affections of some of the other organs, and you will have but little time or thought to devote to the central and primary disease. You will always remember that a fatty heart is a weak heart, and you will regulate the habits of your patient accordingly. In cases where the disease has not long existed and can be traced to a gouty tendency or to lithiasis, a regimen calculated to correct that habit or condition may reasonably be expected to favorably influence the heart.

When associated with obesity, the management of that tendency by proper diet and exercise will be your aim. When existing with chlorosis or anæmia, this state of the blood will demand attention. For general or special reasons, iron, quinine, strychnine, digitalia, belladonna will be ordered and their use countermanded, to give way to other drugs equally useless.

In the great majority of cases, either among the rich or the poor, the diagnosis is not made until the heart is so seriously diseased and disabled that some secondary trouble seems the most pressing, and engages the attention of the physician. This is one reason why the literature of treatment of fatty heart is so barren and so discouraging. The impression seems to generally prevail that a man with a fatty heart is no better than a dead man. I am persuaded that this is like diagnosing phthisis pulmonalis, only upon the presence of extensive excavations and rating its fatality accordingly. The most marked cases of fatty heart are seen in acute fevers, and yet a large propor-

tion recover; again, cases of fatty heart in connection with anæmia are known to recover; again, it is known that fatty heart is only produced by the long continued action of its causes, that the heart seems to have remarkable power of resistance, and succumbs at the end of a long struggle. A due consideration of all these facts leads to the conclusion that the earlier diagnosis of fatty heart is necessary, in order that the results of early treatment may be available for intelligent prognosis.

The Mydriatic Power of Homatropin Hydrobromate.

The following conclusions are arrived at by Dr. S. D. Risley, from experiments detailed in the *American Journal of Science*:—

1. That homatropin hydrobromate, in solutions of two, four, and six grains to the ounce, is competent to paralyze the accommodation.
2. That in from sixteen to thirty hours this paralysis entirely disappears.
3. That dilatation of the pupil accompanies the paralysis and is more persistent; the probable duration being forty-eight hours.
4. That it is no more liable to produce conjunctival irritation than atropia or duboisia.
5. That it produces far less constitutional disturbance than either of the old mydriatics.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The Annual Announcement of the Philadelphia School of Anatomy is a neat pamphlet, which may be had at the School, 1022 Hunter street.

——Several of the carefully prepared studies on chloral hydrate, by Dr. H. H. Kane, have been published, in the form of reprints, and may be had of the author, New York city.

——*Godey's Lady's Book*, for March, has a very pretty steel engraving, from a scene in "David Copperfield," fashion plates, some pleasant stories, etc. Price $2.00 per year.

——In the Fifteenth Report of the Connecticut Hospital for the Insane, Dr. A. M. Shew, Superintendent, describes the management of the patients, and makes, among others, the interesting statement (p. 9), that after the acute stage has been passed, insanity actually tends to *prolong* life.

——Dr. H. A. Wilson, of this city, in a reprint on transverse fracture of the patella, expresses the results of his extended studies of this lesion in these words:—

In closing, I would say that it is my conviction that the hooks are the only scientific method of treating transverse fracture of the patella.

——The Annual Report of St. Michael's Hospital, Newark, N. J., shows the institution in a flourishing state. Singular to say, the eye and ear department has been discontinued "owing to the impossibility of finding specialists to take charge of it." Are, then, ophthalmologists and aurists so rare in Newark? We had no idea of it.

——Two bills are before the Senate of Tennessee, to prevent quackery, etc. A "citizen" sends us a pamphlet commenting on them. One bill provides a State Examining Board. This scheme Citizen condemns. The other bill he believes far better. As such questions are of general interest, we add that the latter bill simply provides that an open register shall be kept by the clerk of the County Court, in which the answers of every practitioner to the following interrogatories shall be filed:—

(*a*) When, where, and with whom the study of medicine was begun, and how long continued.

(*b*) At what school or schools preliminary education was had; in what school medical education; and from what school, and when, a diploma was received, if any has been received.

(*c*) If previously in practice, where and for what length of time at each place.

(*d*) If a member of any medical association or society, where its location and what its name.

This publicity, Citizen thinks, will be sufficient to purge the profession and protect the people.

——A valuable reprint from the *Journal of the Franklin Institute* is a lecture by Mr. Reuben Haines, chemist, of this city, on methods for judging of the wholesomeness of drinking water. He discusses and criticises, in an able manner, the analytical methods of Wanklyn and Frankland. One of his paragraphs especially deserves quotation, as it corrects what we believe is an error current among many professional men, as well as among the laity. It is as follows:—

Those who are familiar with the most recent sanitary experience realize that it is the *quality* rather than the *absolute quantity* of organic matter that is the most important factor in the sanitary judgment of a drinking water. A water which contains a large amount of one kind of organic substance may be much more wholesome or far less unwholesome, than that which contains only a small amount of another kind. It is a matter of actual experience that a water, notwithstanding it contains a large amount of nitrogenous organic matter capable of yielding albuminoid ammonia, may be found to be practically wholesome, or at least may be drunk for a long period without apparently producing any injurious effects; while, on the other hand, a water which contains *even a minimum* of organic substances capable of yielding albuminoid ammonia may nevertheless contain or develop the *materies morbi* or unknown causal "something," of a specific disease.

This distinction, is, it is needless to say, a highly important one, from a sanitary point of view.

BOOK NOTICES.

The Principles and Methods of Therapeutics. By Adolphe Gubler, Professor of Therapeutics in the Faculty of Medicine, Paris. Translated from the French. Phila., D. G. Brinton, 1881. 8vo, pp. 445, half morocco. Price $4.00.

The culmination of the sciences appertaining to medicine is in therapeutics; whatever chemistry, physiology, botany, and the other auxiliary sciences contribute to the knowledge of our profession, it is ultimately with a view to lessen or prevent pain, to shorten disease and to restore to health. Hence it is with justice that therapeutics has figured so prominently in recent literature.

Therapeutics as such may be considered from several points of view. In the work before us the distinguished author has chosen one which may by some be considered narrow, but which he evidently had adopted after long deliberation. It appears to be correctly represented in the prefatory note to this translation, in the following words:—

It is, as its title states, a discussion of the *principles* and the *methods* of therapeutics. It does not take up this branch as an accessory to Materia Medica; nor is it concerned, beyond a moderate extent, with the physiological action of drugs; nor yet has it much to say on the treatment of individual diseases. These topics, which figure so prominently in most works on therapeutics, will be found to occupy comparatively little space in the present one.

Professor Gubler chose to approach his subject from quite other directions and with other purposes. He aimed to represent, from the latest acquisitions of science, and by the aid of the most careful instructions, first, the *methods* which can be most effectively employed in the administration of remedial agents, and next, the *principles* or *processes* by which their remedial action is exerted on the human economy. It is a study founded on clinical, physiological and chemical observations of the actions of medicines in disease, and the technical artifices for their introduction into the organism.

Professor Gubler, it should be remembered, was a disciple of Trousseau. He did not, however, accept the avowed empiricism of this brilliant teacher. He sought to connect the observed results of experience in the action of medicines with the chemical nature of remedies on the one hand and the physiological functions of the body on the other. This effort is conspicuous throughout this work. In some places his explanations are lucid, and impress the reader as forcible and just; in others the reasoning is rather obscure, and the interpreter of nature is probably at fault; but there is always an impress of honest study and great learning.

The matter of the book consists of the last course of lectures which he delivered in the Paris School of Medicine. They were revised from short-hand reports, and have been translated by one of his American hearers, Dr. Halloran, who also adds a biographical sketch of the author, whose death occurred in April, 1879. There are some passages which indicate that the lecturer's meaning has not been fully set forth, owing, probably, to too much abbreviation on the part of the reporter. Allowing for this, the labors of reporter and translator have been fairly done.

The volume is divided into thirty-four chapters, followed by a full index.

The first four chapters are on General Therapeutics. The author here sets forth his views on the general properties of remedial agents, (mechanical, chemical, dynamic action), their effects (physical, chemical, organic) and affinities, the relation of the composition of medicines to their remedial action, etc.

Then follow seventeen chapters on the "avenues and methods for the introduction of medicaments," in which are explained and criticised such means as inhalations, fumigations, atomization, aerotherapy, cutaneous absorption, hypodermic injections, transfusions, injections, etc. Very minute directions are added for such of these as the author especially approves of, as the hypodermic method and transfusion of blood. He concludes the latter subject with these words:—

I am now through with the history of transfusion. It may have appeared tedious to you, but the subject is a very interesting one, and daily growing in importance. Much attention is being bestowed upon it, and if we take the total number of transfusions which have been made, including even those with defibrinated blood, however incapable they were of realizing the hopes placed upon them, since they could but temporarily revive the organism, we shall find that out of 270 cases of transfusion there have been at least 150 successes.

I therefore sum up with the conclusion that when a method is easily applied, is exempt from real dangers, and gives such results when death is almost imminent, it should be recommended, and full credit is to be given to those who are endeavoring to extend its use.

Chapters XXI to XXX are occupied with a discussion of the transformations undergone by medicaments in the organism, their elimination, and their occasional accumulation, together with the proper means of preventing the last-men-

tioned action. This is the most recondite, we may also add, the least satisfactory, part of the work. The principal example which the author takes is arsenic, to the action and transformations of which in the economy, about fifty pages are devoted. While he gives many scattered facts of interest, he appears to us to fall short of demonstrating conclusively the chemical changes of the agent which he assumes. It is rather a foundation to work upon than a completed exposition. He is a full believer in the accumulation of action of remedies, the processes of which he explains ingeniously by several theories.

The final chapters are on "force of habit," "tolerance and intolerance of medicines," therapeutic antagonism, and conditions affecting medicinal action. He does not allow that any complete antagonism does or can exist; partial antagonisms are numerous, but of no great therapeutic importance. The same is true of synergic action. While it is present, and deserves consideration, he esteems it more lightly than do some later writers.

In his last chapter, discussing the effects of climate, he makes a remark which is interesting in these days, when there is, in some quarters, an effort to introduce general bleeding again into practice. He writes:—

> I have already mentioned, in speaking of climates, the much greater capacity of the inhabitants of the north for alcoholic beverages. I could say to you, that general bleeding is better tolerated in the tropics than in the northern climates. It is on this account that the theories of Rasori had so much success in Italy and Greece; more considerable success than with us; more, in particular, than they had in the north.
>
> I am myself an example of the utility of general bleeding. I fell once, in Italy, bathed in blood; I was carried to the hospital of Milan, where they bled me, two, three, even four times per diem; I was longer in recovering from the effects of the bleeding than from those of the wound.
>
> I have often asked myself whether, if these bleedings had not been made, I should not have had tetanus, in such a month as July. General bleeding is well tolerated in southern climates. It is true that it is badly tolerated in marshy districts, because the paludal miasma reduces the inhabitants of such countries to a state of anæmia.

Space does not permit us to extend this notice. What has been said will give an idea of the intention of the author in this work, and the position he designed it to occupy. It is a book to be thoughtfully perused, rather than referred to for particular points; it is a connected whole, which will scarcely attract a superficial reader, but will surely repay a thorough one.

The publisher has done his part well. The paper is heavy and handsome, and the binding—in half morocco—is a pleasing novelty in medical publications.

A Practical Treatise on the Medical and Surgical Uses of Electricity. By George M. Beard, A.M., M.D., and A. D. Rockwell, A.M., M.D., etc. Third edition. Revised by A. D. Rockwell, M.D. New York. Wm. Wood & Co., 1881. Cloth, pp. 758.

This treatise has fairly maintained its position for ten years, as the standard American work on medical electricity. It is large—too large—and might very profitably (to the reader, at least,) have been condensed a couple of hundred pages. The numerous long-winded narrations of cases increase needlessly the bulk of the volume; and there is a good deal of theorizing which has but slight importance. For all that, it remains the most satisfactory treatise for the physician who wants to make a thorough study of electrical treatment.

The present edition has several new chapters; one on exophthalmic goitre, another on the sequelæ of acute diseases, and another, almost new, in reference to the electro-therapeutics of diseases of women. The revision of the other parts has been pains-taking, and probably none of the later conquests, or asserted conquests of electricity in the domain of therapeutics will be found to have been omitted. It is well printed, and the illustrations, nearly two hundred in number, are generally clear and instructive.

A Manual of Diseases of the Throat and Nose. By Francke Huntington Bosworth, A.M., M.D., etc. New York, Wm. Wood & Co. 1881. 1 vol. cloth, 8vo, pp. 427

This work treats of the use of the laryngoscope, diseases of the fauces, nasal cavity and larynx. There are also chapters or sections in it devoted to "taking cold," "mucous membranes," laryngeal phthisis, paralysis of the abductors, and cognate subjects. It is profusely illustrated, there being in all 175 wood-cuts of operations, instruments, etc. They are not very well printed, and the book is not very well written. Cuts, facts, and statements are nearly all borrowed from preceding and better treatises. Of course, there is a great deal in the volume which it is well for the physician to know; but he will learn nothing, or next to nothing from it if he is familiar with the standard treatises on the subject which are already in most libraries of respectable size. There is an "Appendix" of formulas, many in halting Latin and generally very common place. In fact, we feel obliged to say that the volume seems to be a hasty and negligent specimen of book making, by both author and publisher.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE SANITARY REGULATION OF PROSTITUTION.

Lord ARTHUR RUSSELL remarks in one of his speeches that "Necessary changes in political measures are first originated by a small minority, and subsequently written and talked into existence, until what was at first only an idea becomes a moving force." As we belong to the very small minority in this country who have for a long time insisted that some definite measures are necessary in order to protect the community from the spread of contagious venereal diseases, we shall give a sketch of what has been written and talked on that subject within the last few months.

Probably the most important contribution to the subject has been the Report of the Committee on the Prevention of Venereal Diseases, submitted to the American Public Health Association, by DR. ALBERT L. GIHON, Medical Director, U. S. Navy, Chairman, in December, 1880. Having first shown that, in the opinions of the most eminent surgeons, these diseases are both common and dangerous, some statistics of the Navy and Army are given, which establish this fact, that at least one man in every thirteen in the naval service of the United States—last year one in ten; one in every nine in the army —of the negro troops one in six; one in every seven in the British army; and one in every four of the merchant sailors presenting themselves for treatment at marine hospitals and dispensaries, is affected with some form of venereal disease.

The facility of its transmission to innocent persons by kissing, smoking pipes and cigars, sheets, etc., is shown. The results of inspection of prostitutes during the war, in Nashville and elsewhere, are presented. In Nashville—

1. The amount of venereal disease was markedly lessened, so much so that its occurrence came to be looked upon (absurdly, of course,) as an imputation on the care of the examining surgeon. I have more than once known a company officer complain that a man was off duty for disease caught of such a girl, at such a time, and demand that she be sent to the hospital.

2. The women, who were at first rebellious, became quite reconciled to the system. I have known them to come to the hospital voluntarily, desiring to be examined for suspected disease.

3. It was self-supporting, the fees paying the expenses of the hospital.

To-day the Nashville prostitute advertises herself in big gilt letters over her front door, before a blazing light, more conspicuously by far than were she enrolled in a police register, while purblind virtue and false morality stalk by and leave no other guarantee to society than the poor creature's own good sense that her house shall not become a focus of disease as disastrous as smallpox or diphtheria.

In ten years, the surgeon general of the navy is authority for stating, the amount of venereal disease on the Asiatic station has fallen from 425.8 to 112 1 per thousand, a difference of 313.7 per thousand, due to the examination of prostitutes practiced at Hong Kong and in Japan, and the seclusion of infected women in Lock hospitals.

After the report the following resolution was passed, by a vote of 93 yeas to 28 nays:—

Resolved, That the American Public Health Association earnestly recommends the municipal and State Boards of Health to urge upon the legislative bodies of this country the enactment of a law constituting it a criminal offence to knowingly communicate, directly or indirectly, or to be instrumental in communicating, a contagious disease, such as smallpox, scarlet fever, or venereal disease, and giving to the said Boards of Health, and to the State and municipal health officials under their control, the same power in the prevention, detection, suppression and gratuitous treatment of venereal affections, which they now possess in the case of smallpox or other contagious diseases.

In the *Southern Clinic* for Nov., 1880, an attorney at law, Mr. F. E. ANDERSON, has an able review, historical and critical, of repressive enactments considered strictly from a legal point of view. He maintains that they are strictly in the purview of the government of the States, and argues that it is the duty of the legislative powers to pass such acts as are necessary to the health of the community. He asks, how can a philanthropist oppose a movement which, if it cannot kill crime, yet can rob it of the sting of disease? The legislation that he would propose runs as follows:—

That each corporation shall list the name, color and residence of each strumpet in its limits. It shall be a matter of police cognizance, with a municipal supervisory committee. There shall be one competent physician to each district. He shall examine each inmate of every house of ill-fame in his said circuit at least once a week. If he shall find any one unsound, he shall transfer her to a ward in the hospital, where she shall remain until a cure be effected. A stated tax shall be levied upon each prostitute, and the proceeds resulting therefrom shall be applied to defray all expenses arising therefrom. It shall be the duty of the person unsound to report to the committee, through the expert, the name of the one who may have infected her. If a medical examination sustain her charge, the accused, (unless he can prove an *alibi*) shall be fined and imprisoned. A false statement against one who is innocent shall be likewise punished; as shall also any disturbance of the public peace, in which case there shall be the usual powers of arrest.

This suggestion of a tax upon each prostitute has a jarring sound on some sensitive ears. It is called "licensing" prostitutes by the State; these innocents not being aware that all the public houses are regularly mulcted, as it is at present, only that the indirect tax they thus pay does not go into the public treasury, but into the pockets of the "force" and informers. Frightened by this bugaboo, the editors of the *College and Clinical Record* offer the following singular suggestion to legislators:—

Upon the complaint of a man, supported by oath, that he was inoculated with venereal diseases by a certain woman, the said woman shall be arrested and sent to a hospital for examination. If the accusation is found to be true, she shall pay a fine of not less than twenty-five dollars into the State treasury, and be detained in the hospital until well. Moreover, the keeper of the house in which the disease was acquired shall be made to pay a fine of not less than one hundred dollars, or undergo three months' imprisonment in the county jail; and furthermore, the owner of the house or property in which said inoculation occurred shall be fined not less than two hundred dollars, which shall be a lien upon the property until discharged according to law.

Nothing could be more degrading than such a statute; nothing more cruel to these poor and defenceless women than to put them in the power of men base enough thus to swear publicly against them We shrink with horror from such suggestions. Shall no recognition be had of the fact that prostitutes are *human beings*, often friendless, ignorant, poverty-stricken, but not for that account to be harried by the worst and lowest class of males in a community, under the sanction of law?

A thoughtful and learned article on the subject appeared in the *Canada Medical Record* for Dec., 1880, from the pen of Dr. CASEY A. WOOD, physician at the Women's Hospital, Montreal.

The general principles which he advocates appear to us so temperate, judicious and suitable to the exigencies of the case that we indulge in a long extract from his article, the part which contains his suggestions to meet the difficulty:—

Physicians should have power to communicate to the chief of police the names of those prostitutes from whom any of their patients has contracted disease. The medical man should satisfy himself that the patient is in a position to state positively when, where, and from whom, he caught the contagion, and that the female is in the habit of distributing her favors promiscuously or for money. Where there is any doubt about the last two points the suspected woman should have the benefit of it, but in the majority of instances the police would be able to settle the question satisfactorily. Having satisfied himself on these points the chief should have power to serve a notice on the woman to forward to him, within twenty-four hours, a certificate from a regular practitioner, of her being in a healthy state, or else, if she be a common prostitute, to present herself at the hospital for treatment. In case of those who are not "common," in the ordinary acceptation of the term, *i. e.*, who do not practice their trade openly, and do not live in brothels, it would be justifiable to accept a certificate from a regular practitioner that the woman is under treatment by him, and that he would use every means in his power to prevent her from cohabiting until she recovered. In this way (for all these proceedings would be kept secret, and neither the name of the male sufferer nor of the female patient would be divulged) scandal would be prevented in the case of occasional and otherwise "respectable female.

For the other class, those who are generally recognized strumpets, neglect or refusal to furnish a proper certificate, or to undergo treatment

if diseased, would justify their arrest and forcible detention in special wards of the hospital for a time discretionary with the officials in charge. Action of this kind would encourage the voluntary system and leave coercion as a *dernier ressort*. It would incite women to apply for treatment at once, and not wait until they were compelled to quarantine themselves by the strong arm of the law. It would respect the respectable, but punish the guilty. Voluntary patients might be allowed to leave the hospital when they desired, but they should be warned that any attempt to return to their trade until fully cured would involve their semi-imprisonment in the "coercion" wards of the hospital, and cut them off from all the privileges of the voluntary side. Examinations should be made voluntary in a Dispensary attached to the hospital, and a small fee (in Hamburg, where the regulation system is in vogue, it is only a mark) should be charged. As soon as the intention of periodical examinations was known they would begin to be appreciated, and, in time, the great majority of the prostitutes in the city would be likely to present themselves for medical inspection. A larger fee might be charged for attending the prostitutes at their houses. Certificates of good health might be issued if asked for by the women, but it must be understood that they are not considered necessary. It would, of course, be out of the question to admit students to any part of the hospital except to the coercion wards. This portion of the institution, being in some sense a city house of correction, would have a good claim for civic support, and in that case might be overlooked by a local inspector. In the event of a hardened sinner persisting in spreading venereal diseases instead of applying to hospital for relief, and necessitating repeated arrests, it would be justifiable to have her registered and examined by the medical officer not less frequently than once a week. This would be a greater punishment to her, in view of the treatment of her other sisters in vice, than imprisonment.

To complete these suggested regulations, it ought to be made possible for an inmate of a house of ill fame to abandon her life of infamy free of any claim for board, liquors, clothes, etc., the brothel-keeper may have upon her. It is, of course, to the interest of procurers and keepers to exert as great an influence upon their stock-in-trade as possible, and for this purpose many of them try to keep the girls in debt, so that they are compelled to continue in their old ways. It would be a good idea, also, to subject brothel keepers to a heavy fine, if it be proved that they allow any of their women to remain in their houses after becoming diseased. The proceeds of such fines would go to defray the expenses of the hospital.

The advantages of the measures above specified recommend themselves, because: (1) the legislation involved is not a one-sided treatment of woman, as if she were made for man simply to gratify his lust upon; (2) they leave a way open to those erring ones who desire to reform; (3) women are not compelled, except as a last resort, to undergo a degrading periodical examination by public officers; (4) the system does not condemn to a life of hopeless infamy those who err temporarily, or who are seduced by designing men; (5) they provide for clandestine prostitution; (6) they are voluntary to a very great degree, and attempt to do by kindness what coercion has, over and over again, failed to accomplish; and, lastly (7) they do not violate the sanctity of private houses, as the system of forced registration is sure to do.

These suggestions are well matured, and appear to combine the necessary stringency without placing a too severe power in the hands of police or health officers, and it does away with the appearance of "licensing" prostitution, while yet it obliges it to contribute to its own protection against disease.

Standing almost alone, in reference to this subject, is Dr. F. Cadell, Lecturer on Syphilology in the Edinburgh Medical School. In a paper recently read before the Medico-chirurgical Society of Edinburgh, he took the ground that "Syphilis is not a sufficiently serious disease to require any special legislation." That a specialist in syphilis should advance this opinion, can only be explained by supposing that the disease, as he has observed it, has presented itself only in its milder forms.

From the above extracts and comments, it is plain that this question, equally important to the health and the morals of a community, is attracting the attention it deserves, and will certainly be brought, in one form or another, under the control of social law.

An interesting discussion of the general subject took place last August, at the International Congress of Hygiene, held at Milan.

Among the papers read at the special sittings of the Congress, was one by Dr. Catella, of Turin, on the legislative measures to be taken for the limitation of the spread of syphilis. A few of the speakers, as Dr. Pini, of Milan, would have us look to a general elevation of the moral tone of society rather than to repressive means. Some would endeavor to establish an international agreement, for the inspection of passengers—we suppose, endorsing their passports with the required certificate of freedom from disease (!)—while Dr. Da Cunha-Bellem, of Lisbon, would convert every medical man and chemist, every Government official and master, into an inquisi-

tor, and every man and woman into an informer, until the disease had been chased from the face of the earth(!). The general feeling was, however, expressed in a resolution, which, leaving the enforcement of Contagious Diseases Acts, so far as regards prostitutes and soldiers, to the local authorities, but realizing the extent to which syphilis is spread by the sailors of the mercantile marine, called on the governments of Europe to combine in demanding a clean bill of health of every ship leaving or entering a port.

Notes and Comments.

Epigastric Pressure in Obstinate Hiccough.

M. Deghilage, of Mons, we read, in the *Journal des. Sci. Med. de Louvain*, January, 1881, was called to a young lady suffering from very violent hiccough, with spasm of the glottis. The patient had been over an hour in this state and was unable to articulate a syllable. There was no fever, no signs of heart trouble; the only cause that could be assigned was, that the patient had the lower limbs chilled a few days previously, during her menstrual period. Inhalations of vinegar and Hoffman's anodyne, and the application of sinapisms had been tried, without effect. Recalling Rostan's precept for such cases, M. Deghilage applied the palm of the hand to the epigastrium, and exercised strong pressure; there was slight amelioration, the movements were less convulsive and the dyspnœa less intense. A large pad of linen was then applied over the epigastric region, and pressed strongly inward by means of a bandage passed around the body. In a very short time complete relief was obtained; the pad was left several hours in position, and when it was removed the symptoms did not return and have not since reappeared.

Carbolic Acid as an Antipyretic Agent.

M. Desplats, of the University of Lille, has presented a note on this subject to the Belgian Academy of Medicine.

Because of the antiseptic properties of carbolic acid, the author considered that it would prove of benefit in typhoid states, and has for the last three years administered it in typhoid and the various septic fevers. In his memoir he cites three cases where the acid was administered, generally in enema, commencing at the dose of ¼ gram of the acid to an enema.

In the first case the temperature, at 40.8° (Centigrade) previous to the administration of the enema, fell within the course of an hour to 39.8°. The next day ½ gram of carbolic acid was used in enema, and the temperature was reduced one degree and three-tenths in somewhat over an hour; during the night successive enemata were administered, each containing ¾ gram of the acid; perspiration always occurred in about 15 minutes after the enema was administered, and when this ceased (in somewhat over an hour generally), another enema was administered, and in this way the temperature was reduced before morning to 37.7°.

The same evening, however, the temperature had again mounted to 41° (C.); the enemata were repeated through the night, as before, and with like result; it was found necessary, however, to augment the proportions of carbolic acid. By this means the temperature was kept low, but whenever the enemata were neglected it soon mounted again.

The young man made a good recovery, as did also two other patients on whom the experiment was repeated. M. Desplats found that carbolic acid was tolerated in large doses, from five to twelve grams per diem in one case, ninety-one grams being administered from the second to the seventh of August, in another. He has drawn the following conclusions from his experiments: 1. Carbolic acid administered in sufficient doses has always the effect to lower the temperature. 2. The temperature may be kept low by repeated doses; the physician being thus able to modify à volanté the temperature. 3. The doses of carbolic acid ordinarily considered toxic are not so; the patient may absorb eight, ten, twelve grams without danger. 4. The rectum is the best way for the introduction of the medicament; more than two grams should not be administered in one enema, and this dose should be gradually reached, commencing with one-fourth of a gram.

Tardy Expulsion of a Dead Fœtus.

During the recent discussion in the Paris Academy of Medicine, on the imputrescibility of the dead fœtus while the membranes remain intact, M. Depaul cited the following case, of recent occurrence in his service:—

A young woman, twenty-two years of age, entered the service on January 25th, saying that after several rapid and convulsive movements, on December 24th, the fœtus had given no further signs of life; her breasts, which had become enlarged, went back, and the abdomen seemed to sink. M. Depaul found that the child was

dead, but it was not expelled from the uterus until January 10th, that is, seventeen days after its death.

The epidermis was peeled off in several places; the bones of the head loose, as if dislocated; the cord of a dark-red color, but not the least sign of putrefaction was present.

M. Depaul denies that a fœtus dead under these conditions, with the membranes intact, is a source of danger for a twin or for the mother. He holds that when a child thus perishes the circulation of its department is interrupted, the vessels are obliterated, and the blood of a living twin cannot then penetrate into the vessels of the dead fœtus.

Special Reports.

VI—ON ANÆSTHETICS.

A variety of interesting matter on anæsthetics and their uses has appeared in the journals during the last six months, besides the two recent and extensive treatises of Turnbull, in America and Rottenstein, in France.

Relative Action of Anæsthetics.

It is, perhaps, known to most readers that in 1877 a committee was appointed by the British Medical Association to investigate the action of anæsthetics. A complete account of their investigations from that date down to the present time is printed in the journal of the Association for December 18, 1880. It is long and thorough, giving a complete account of the various substances alleged to have anæsthetic effects, and especial investigations into ethidene dichloride, chloroform and ether. Their respective influence on the pulse-respiration ratio, on blood pressure and on pulmonary circulation, are set forth. Space does not permit us to give even an abstract of these important studies, but the *practical rules* with which the Committee concluded their report are too valuable to be omitted.

They are as follows:—

1. It is not only necessary to watch the effect of the anæsthetic upon the pulse, but it is also requisite to have regard to the respiration. We must not only take into account the danger of sudden stoppage of the respiration, but must also remember that, in the event of abnormal increase of respiratory movements, it may become essential, for the safety of the patient, to temporarily discontinue the administration.

2. Owing to the tendency of chloroform and ethidene—particularly chloroform—to reduce the blood pressure suddenly, not only during the administration of these agents, *but also after they have been stopped for some little time* (a source of serious danger), it is necessary for the person who has charge of the administration of the drug to be on the lookout for symptoms of this occurrence, both during the time the agent is being given, and for some time after the patient has recovered from its more evident effects.

3. The danger of death from stoppage of the respiratory functions, must be borne in mind in every case in which anæsthetics are given; but, of perhaps greater importance is the danger from interference with the proper action of the heart—particularly when it is remembered that, by artificial means, we can combat the former contingency. It might even be advisable, in certain cases, to introduce a tracheal tube by the mouth, so as to enable us to force air into the lungs by means similar to those adopted in experiments with animals; or, in circumstances where such a procedure was impracticable, tracheotomy might be performed, with the same object in view. Artificial respiration should be continued, even though all evidence of cardiac action has ceased.

4. As regards comparative danger, the three anæsthetics may be arranged in the following order: chloroform, ethidene, ether; and the ease with which the vital functions can be restored may be conversely stated, thus: the circulation is more easily re-established when its cessation is due to ether than to ethidene; and when the result of ethidene, than when chloroform has been used. The advantages which chloroform possesses over ether—in being more agreeable to the patient and more rapid in its action, in the complete insensibility produced by it, and the absence of excitement or movements during the operation—are more than conterbalanced by its additional dangers.

5. The chief dangers are: (1) sudden stoppage of the heart; (2) reduction of the blood pressure; (3) alteration of the pulse-respiration ratio; (4) sudden cessation of the respiration. The danger with ether approaches from the pulmonary rather than from the cardiac side—so that, by establishing artificial respiration, we have a means of warding off death. Its disadvantages are to a great extent, obviated by the use of ethidene; while the dangers of chloroform are also reduced to a minimum.

Suggestions for the Safe Administration of Anæsthetics.

A suggestion to render the administration of chloroform safe, is made by Dr. A. Crombie, in the *Practitioner*, Dec., 1880. He begins the chloroform in the usual way, by inhalation, and immediately injects, with the hypodermic syringe, twenty minims of the officinal solution of muriate of morphia. This greatly prolongs the anæsthesia, so that a very small quantity of chloroform suffices to keep it up afterward, half a drachm to a drachm being usually enough to keep the patient insensible for thirty to forty-five minutes. In long and difficult operations, especially about the mouth and face, this is no small advantage; thus, in removing the right upper maxilla, Dr. C. was

enabled nearly to complete the operation without the further administration of chloroform from the time that the patient was declared "ready." Vomiting is rarely seen when this method is followed. Chloroform asphyxia also seems to be prevented. In 600 cases, Dr. C. has only once seen it, and in that instance some of the usual precautions had been neglected. Paralysis of the heart, too, is less apt to happen, the risk of the occurrence of this accident, and of asphyxia as well, being lessened in proportion to the smallness of the dose of the anæsthetic required to cause and reproduce the anæsthesia. It is pointed out that this method makes chloroform as safe to use as ether; and that in tropical countries, especially India, where operations have to be performed at a temperature very little below the boiling point of ether, there is practically no choice of anæsthetics.

This suggestion, however, and similar ones for combining anæsthetics with opium preparations meets a critic in Dr. E. H. Jacob, who writes to the *British Medical Journal*, in January of this year, the following warning:—

May I utter a word of warning on the combined effects of ether and opium? Several cases have recently come to my knowledge—the details of which, I hope, will soon be published—in which death followed a short time after the administration of ether to patients under the influence of opium. In the table of deaths from ether, which you have just published, out of six cases in which death could be directly attributed to the anæsthetic, two were cases of hernia; and, therefore, most probably under the influence of opium. Whether it be a case of this kind, or morphia be given subcutaneously, in order to obtain the benefits of "mixed anæsthetics," ether is not without danger; and the patient should be carefully watched, after the operation, till complete awakening has taken place. In the recent volume of Billroth's *Deutsche Chirurgie*, which is devoted entirely to anæsthetics, Dr. Kappeler, from an experience of twenty-five cases, speaks strongly against the practice of mixed anæsthesia by morphia and ether; but allows that by morphia and chloroform to be open to less objection. Whether death occurs by the ether deepening the morphia narcosis, or by the morphism preventing the patient from clearing his bronchi from the secretion provoked by the ether, I will not undertake to say. It appears to me to be a very proper question for physiological experiment. Similar warnings have been uttered before against this form of "mixed anæsthesia;" but I do not think public attention has been called before to this explanation of deaths in hernia operation under the use of ether.

Dr. E. L. Hussey, in the London *Med. Times and Gazette*, Dec. 18, inveighs strongly against the use of the towel or napkin. Referring to a fatal case, in that country, he writes:—

It is impossible to resist the conclusion that in many of the unfortunate cases which have been under public notice the patient lost his life through carelessness: that, in fact, he was smothered with the apparatus in which the anæsthetic was given. In this case from America we have again the story of the towel. It is the same in almost all the fatal cases: a towel, a napkin, a fold or two of lint, is used; something, in short, which of itself is a bar to the natural process of respiration. The symptoms which precede the stoppage of the pulse and the breathing are not always reported completely; perhaps they are not always observed. Artificial respiration fails to restore life.

A well made *inhaler*, he believes, should always be employed.

A combined method of administration is recommended, for its convenience and safety, by Mr. Woodhouse Braine, F.R.C.S., in the *British Medical Journal*, December, 4. He writes:—

The quickest, and, in my opinion, the best, method of giving ether is to administer nitrous oxide till the patient is completely anæsthetized, and then to change the face-piece without allowing the inhalation of any air whatever. During the first few respirations the larynx resents the ether-vapor, and they are somewhat jerky and spasmodic; but the larynx soon becomes accustomed to the irritant, the breathing becomes full, easy, and regular, and there is a complete absence of struggling. When the struggling does occur, the movements are generally referable to dreams which the patient is having; and when he wishes to alter the position of his limbs, or to sit up, in pursuance of the nature of his dream, forcible prevention only makes him struggle more violently to accomplish his object, which, if effected in the first place, would have had no practical result, and he would have dropped back into the former recumbent position of his own accord. Should this struggling take place, no attempt should be made to hold the patient in any one position; his limbs should be allowed to move about freely, and he should be permitted to sit up, if he desire to do so—only preventing him from pulling off the face-piece.

But, in addition to the trouble saved by not having to hold a patient, the risk of a fatal result, especially when administering chloroform, is much less; for, if the patient be allowed to move freely, the heart has comparatively little work to do, compared with the strain on it which exists when it has to drive a column of blood through vessels which have rigid muscles on each side of them; and, again, this very struggling increases the venous flow, and tends to gorge the heart with venous blood.

Anæsthesia by Rapid Breathing.

It is well known now that by increasing the number of respirations up to one hundred or thereabouts per minute, teeth have been extracted and other minor surgical operations performed without pain.

A case in point is reported by Surgeon Major

Harman, in the Baltimore *Medical Journal*, Dec. 11th. He writes:—

I was fortunate enough yesterday to have an opportunity of adopting the new method of analgesia in cutting out a fatty tumor, of the size of a small walnut, from over the anterior upper fifth of the tibia. The leg, only grasped by a hand at the ankle, did not move throughout the dissection over the tender region of "the shin." The patient, who was nervous, very anæmic, and debilitated from the effects of severe ague, avers that "he felt nothing except the stitching;" and I could not have ventured to use chloroform, being alone; the patient's condition also rendering this anæsthetic unadvisable.

The explanation of this curious fact appears to be that excessively rapid breathing disturbs the action of the system in such a way that oxidation is impaired and carbonic acid is increased unduly in the blood, to the extent of producing its characteristic benumbing effects on the sensory nerves. Some experiments illustrating this were reported by Prof. H. C. Wyman, M.D., of the Detroit Medical College, in the Detroit *Lancet* for Feb., 1881. One of these was as follows:—

A small terrier was fastened to a table, a small tracheotomy quickly made, without anæsthetic, the nozzle of a close-working Davidson syringe introduced into the trachea, and air was forcibly driven into the lungs. The chest was quickly distended and soon all efforts at respiration ceased. An incision made in thigh to examine crural artery and nerve, which was strongly pinched, elicited no wincing. The crural artery was found pulsating, demonstrating that circulation, so far as heart factor was concerned, was normal. With syringe nozzle in trachea, cries, as result of pinching crural nerve were of course impossible, but the spasm of muscle usually observed when nerves are irritated were absent. Next, the nozzle of syringe was withdrawn, and while there were yet no respiratory movements, an awl was thrust through the skull upon the fifth nerve, the trunk broken, as manifested by change in pupil, but no cries or other signs of pain were noticed, notwithstanding. This is known to be one of the most painful vivisections. The dog after a few minutes recovered respiratory movements, but in the course of half an hour had several epileptic seizures. Twenty-four hours later he was dead. Autopsy showed that the pons had been broken by the awl, and that there was considerable extravasation of blood about the medulla and cerebellum. Clearly, death was not due to the artificial inflation of the lungs.

The Protoxide of Nitrogen.

Interesting studies have recently been made on the protoxide of nitrogen. The recent researches of Golstein and Zuntz, conducted in the laboratory of Pflüger, have shown that a complete narcosis is only produced and maintained with protoxide of nitrogen in the absence of oxygen; that is to say, it is the combination of asphyxia with the respiration that produces complete narcosis; and they have shown that the pressure of blood, and the frequency of blood and the heart-beat, change under the influence of the respiration of protoxide of nitrogen in the same manner as under the frequency of asphyxia by suffocation.

These researches have been modified by the now well known experiments of Dr. Paul Bert, of Paris, who has succeeded, by making the patient breathe in an apparatus where the pressure is carried as high as two atmospheres, in enabling him to respire a mixture of protoxide and oxygen under such pressure as enables him to obtain complete anæsthesia, while maintaining in the blood the normal quantity of oxygen. To enable a sufficient quantity of the gas to penetrate into the organism to produce a complete insensibility, it is, according to M. Bert, indispensable that the tension of the gas be equal to one atmosphere. It is sufficient to augment the pressure under which respiration of the gas is carried on by one-fifth of an atmosphere, and to cause the patient to inspire a mixture of five-sixths of protoxide of nitrogen and one-sixth of oxygen, to obtain complete anæsthesia without asphyxia. For this purpose a special apparatus has been constructed, which is formed of a diving-bell, under which operations are carried on with this method of mixed anæsthesia for prolonged periods of an hour or more—the operator, the patient and his assistant being all enclosed in the pressure chamber.

A full account of these experiments can be found in the work recently published at Paris, *Traité d'Anœsthésie Chirurgicále*, by Dr. Rottenstein.

All persons are not subject to the anæsthetic influence of nitrous oxide. At a meeting of the Odontological Society of Great Britain, in December last, Mr. George Lyddon read notes of half a dozen such cases. One, a clergyman, apparently healthy, though he suffered severely from dyspepsia, and engaged in the active duties of his profession, took the gas; he exhibited no signs of nervousness whatever, but inhaled it freely and well. After taking a considerable quantity he declared it was having no effect upon him; and, as this was evidently the case, the attempt was abandoned, and the teeth were extracted without the use of any anæsthetic. Mr. Lyddon estimated that the patient had inhaled about twenty gallons of the gas, but it had no more effect upon him than if it had been common air. The apparatus appeared to be in perfect order; it acted quite satisfactorily with the next patient

operated on, and Mr. Lyddon could not give any satisfactory explanation of the failure.

Treatment of the Anæsthetic Narcosis.

Several novel or partly novel plans of treating the narcosis have been mentioned. Professor Schirmer mentioned a simple one in the *Centralblatt für Augenheilkunde*, last year. This method consists in *irritating the nasal mucous membrane.* It has long been known, at least to physiologists, that the fifth nerve retains its sensibility longer than any other part in narcosis, and that reflexes may be induced through this nerve when other irritations fail. Professor Schirmer uses simply a rolled piece of paper, which he turns in the nose. In dangerous cases he dips the paper into ammonia.

Dr. F. W. P. Jago (*British Medical Journal*, December 11th, 1880), thinks that it would be proper to try *acupuncture of the heart*, by introducing a needle between the ribs near the apex of the heart, and pricking it slightly. He thinks it would not be dangerous.

Another plan he refers to is by *percussion of the heart.* He gives this instance:—

Some time ago, a dentist, who had given bichloride of methylene, sent for me. I found a young and very healthy-looking woman lying back, insensible, in the dentist's chair. The pulse and respiration had ceased for so alarming an interval that her case looked very bad indeed. Holding her wrist, to feel her pulse, it occurred to me to give her one *sharp, very sudden* blow with my knuckles over the region of the apex of her heart. This appeared to produce the desired result: the patient gasped, drew a good inspiration, and a pulsation was at once felt at the wrist. But this is only one case; and, as one swallow is no proof of summer, it may not be a true instance of cause and effect after all; yet I feel sure that that sharp, rapid blow over the apex of the heart saved the patient's life.

Following this suggestion, another correspondent proposes stimulation by "Corrigan's button," a button-shaped piece of metal heated in hot water and applied momentarily to the cardiac epigastric regions.

Special Anæsthesias.

Anœsthesia of the Larynx.—At the International Laryngological Congress, at Milan, last summer, M. Rosbach explained his method of anæsthetizing the larynx. It consisted of the hypodermic injection of 6 milligrams of morphia on both sides of the larynx, at the point of entrance of the superior laryngeal nerve. M. Krishaber doubted whether a local anæsthesia could be obtained by so weak an injection; the effect was more probably due to the general action of the medicament. He himself had only once had occasion to produce anæsthesia in a case of polypus of the larynx, without, however, finding any satisfactory result follow.

A solution of carbolic acid and chloral hydrate applied with a towel is now popular in England.

Anœsthesia during Operations on the Mouth.—In the *Lancet*, November, 1880, page 813, Dr. Macewen reports the fourth of a series of cases where, in a man, aged 45, he had excised a cancerous tongue, giving chloroform by a tube introduced through the glottis. The tube projected several inches beyond the mouth, and the anæsthetic was given continuously without interfering with the operator.

Mortality From Anæsthetics.

A list of deaths from anæsthetics, which occurred in the decade 1870—80, in Great Britain, printed in the *Brit. Medical Journal*, Dec. 1880, shows:—

From chloroform	101
" ether	11
" chloroform and ether	7
" methylene	10

This table does not, however, tell so hardly against chloroform as appears at first sight, as it must be remembered that chloroform is much more popular in England than is ether; and if we suppose it is ten times as much so, then the mortality from the two would be nearly the same. As to just in what proportion it is given, there is no means of knowing.

According to a letter in the same journal, from Dr. Jacobs, chloroform in England is fatal, at the most, once in 3000 cases. Considering how carelessly it is often given, this is not a high mortality. But it does not, as some seem still to think, depend altogether on carelessness. Thus a fatal accident occurred at Vienna (*Allg. Wiener Mediz. Zeitung*, No. 48), in the *klinik* of Prof. Billroth on the 25th of November. An exceedingly anæmic patient, fourteen years old, who was subjected to deep narcosis for the sake of rectifying a spontaneous luxation in the left hip-joint, after he had endured osteo-myelitis in the right lower extremities, died suddenly, and could not be resuscitated, in spite of all efforts. The narcosis was produced in the manner usual there, by the inhalation of a mixture of chloroform, ether, and alcohol (100 : 30 : 30). Probably the patient was too anæmic to support the change in the blood from the anæsthetic mixture.

Prof. Brown-Séquard has lately shown, as we see in the *Gazette Hebdomadaire*, Nov., 1880, the possibility of killing animals in perfect health by applying chloroform to the skin. He found

that in all cases in which that liquid had induced loss of consciousness, anæsthesia, and a notable diminution of the temperature, of the movements of the heart, and of the respiration, death may be certainly produced by continuing to pour chloroform on the skin. Animals may almost always be placed in this dangerous condition of stupor and general resolution which will lead to death if the application of chloroform be continued. Some animals, however, have proved refractory, but even in these a portion of the phenomena which are generally produced is observed.

Anæsthesia in Labor.

This is discussed by Dr. Reed, in the Detroit *Lancet*, December, 1880. Dr. Reed does not commence the use of the anæsthetic before the os is dilated to at least the size of half-a-crown, before which the woman will bear her pains with but little complaint. He has found that the danger of delay in labor is much more liable to occur from the use of an anæsthetic too early in labor, than from the too free use of it after labor has advanced. It may be laid down as a rule before commencing the use of an anæsthetic to give a dose or two of the fluid extract of ergot, which will not only facilitate the uterine contractions, but act as a safeguard against any tendency to hemorrhage. He has lately used quinine in from three to five grain doses, or the two combined, and has obtained invariably good results. Dr. Reed prefers the following mixture as the best and safest anæsthetic to use:—

℞. Chloroform, ℥ ij
Sulphuric ether, ℥ ij
Absolute alcohol, ℥ j.

The subject was discussed last fall by the St. Louis Obstetrical Society, and considerable difference of opinion elicited. In the *Obstetrical Gazette*, Jan. 1881, Dr. D. M. Culver, of Indiana, believes that an anæsthetic often weakens the labor pains. He writes:—

I advise young physicians to use anæsthetics only in extreme cases—threatened convulsions or manual delivery—and let natural labors rest with nature's aid. As to ether, I deem it as unsafe as chloroform. I am satisfied, after considerable experience with it, that there is more danger of paralysis of the lungs from its use than from chloroform, and I *know* that it is better calculated to embarrass the physician than chloroform, for its effects are not so quick nor so complete.

Generally speaking, there can be little doubt but that chloroform, properly administered, is the better anæsthetic in labor.

Anæsthetizing During Sleep.

Dr. J. N. Quimby reports, in the last volume of the *Transactions of the American Medical Association*, some experiments to ascertain if a person can be chloroformed during sleep. He found no difficulty in doing so, and reaches the conclusion that any one moderately skilled in giving the anæsthetic can do so without waking the patient. This demonstration has important medico-legal bearings; and also, as he suggests, it may be advantageously employed with children and nervous persons, thus avoiding the excitement and unpleasant anticipations they have of the operation.

Correspondence.

Corrosive Sublimate from Calomel.

Ed. Med. and Surg. Reporter:—

I notice in your issue, February 19th, an answer by H. W., of Ohio, to the query of J. G. Jr., of Alabama (in reference to effect of calomel administered with chlorate of potash), which relates a case of poisoning by tinct. ferri chlor., et potas. chlor. given soon after a dose of calomel.

If H. W., will reflect, I think he will conclude that the tinct. ferri chlor. formed with the calomel the poisonous bichloride of mercury. Chlorate of potash parts very reluctantly with chlorine, but more readily with oxygen. Some nine years ago I left calomel and chlorate of potash to be given to a baby every hour, alternately. During the day, while thinking over the child's sickness, it struck me that I had given medicines that were not only incompatible, but poisonous, to the child; and, as fast as my horse could take me, I repaired to the place (much to the family's surprise), and found the child—better.

For arsenic poisoning, a very handy and efficient antidote can be made, by adding baking soda to dilute tinct. of iron, forming sesquioxide of iron, and common salt. This illustrates how readily ferric chloride adds its chlorine to another substance. C. H. Shivers, M.D.

Haddonfield, N. J.

Chloral in Poisoning by Strychnia.

Ed. Med. and Surg. Reporter:—

On the night of 2d instant I read and studied with interest and care the article of Dr. Kane, on Chloral in Cases of Strychnia Poisoning, the more so as, about two years ago, I had great difficulty in relieving an accidentally poisoned patient, who supposed it to be quinine. It was done, however, by bromide of potassium and fluid extract gelseminum. A persistent and torturing neuralgia followed this case for weeks afterward, mostly confined to the head and intercostal muscles.

About 4 P.M., 3d instant, a messenger came hurriedly to my office door, urging immediate attendance on a young lady friend of mine in the outer limit of town. Our pastor met me with blanched face, saying, "She has taken strychnine."

She had gone through one fearful convulsion, and as I entered the room went into another,

the most horrible I ever saw, her perfectly empurpled countenance and faintly gasping respiration indicating apparently the death struggle. Just balancing for awhile, the tide of life began again to flow. To the emetics already given I gave more, as soon as practicable, and a hypodermic of ¼ grain of morphine, to steady her, and ordered at once, from the apothecary a solution of chloral, and another of bromide of potassium. In thirty minutes' time I had it, and gave her thirty grains of each. Just as she swallowed it, another convulsion came on, which lasted just fifteen minutes, gradually becoming milder towards its close, as the antidote began to do its work. As soon again as she could swallow, I gave thirty grains more of chloral, after which there were no more convulsions. At six I left her, with proper instructions with a capable nurse, who reported frequent vomiting during the night, but not even a rigidity; oil was ordered at 7 A.M., 4th. This finished the treatment; next day she was up, only complaining of soreness. This timid and sweetly disposed girl had been melancholy for three months, grieving for her dead mother. Supposing it to be morphine, and "desiring to go into a sleep from which she would never wake," she took not less than three, probably, five grains of strychnia. It may be interesting to note the fact that this poison had been lying in a paper in a drawer for certainly twenty years, and had lost none of its medicinal properties.

EDWARD H. SHOLL, M.D.

Gainesville, Ala., Feb. 17th, 1881.

Pathology of Tubercle.

ED. MED. AND SURG. REPORTER:—

In the *Transactions* of the American Medical Association, page 344, paragraph 10, I read:

"Tubercle is a secondary product—a result from embolism, *caused by thrombi of fibrin filaments*—of the massal corpuscles, and from the mechanical and chemical effect of the embolism on the nutrition."

Please have the paragraph so worded that the ordinary reader may be enabled to grasp the idea. Being interested in the subject matter, the inquirer is anxious to thoroughly understand what has been written. J. W. C. O'NEAL, M.D.

Gettysburg, Pa.

[We shall be glad to hear from Dr. Ephraim Cutter, the author of the article quoted from, a more extended explanation of this somewhat mysterious definition. ED. REPORTER.]

News and Miscellany.

The Bellevue Hospital Medical College Weakens.

We have received, with regret, a circular from the Faculty of the Bellevue Hospital Medical College, New York, of which the following is an extract:—

"The experience of the session of 1880–81 has led the Faculty reluctantly to the conclusion that to persist in the requirement of attendance during three courses will be to incur a risk, as regards the interests of the college, which they do not feel justified in assuming; and the purpose of this announcement is to state that, after the present session of 1880–81, attendance during a third session will be optional, and not obligatory. This college, like most American medical colleges, is self-sustaining; and the special provisions for instruction, which have been and will continue to be maintained, call for a large expenditure of money, as well as of time and labor. With an undiminished desire to continue the requirement of three sessions, and with not less willingness than heretofore to make whatever personal sacrifices may be necessary, the Faculty feel obliged, by a proper regard for the prosperity and usefulness of the college, to return to the requirements for graduation which were in force prior to the session of 1880–81."

We have observed that there has been less "push" in Bellevue in the last few years; less advertising, diminished announcements, etc.; and this, no doubt, in part explains the failure. It is lamentable, for all that.

Northern Medical Association, Philadelphia.

The following is a list of the officers of the Northern Medical Association elected for the year 1881:—President, Dr. Jas. B. Walker. Vice President, Dr. Henry W. Rihl. Treasurer, Dr. E. E. Montgomery. Recording Secretary, Dr. I. G. Heilman. Corresponding Secretary, Dr. J. T. Eskridge. Reporting Secretary, Dr. L. Brewer Hall. Counsellors, Dr. N. L. Hatfield, Dr. Wm. M. Welch, Dr. L. Brewer Hall, Dr. Robert J. Hess, Dr. E. R. Stone.

QUERIES AND REPLIES.

Dr. J. A. B., of Pa., inquires (1) whether it would injure the medical quality of dialysed iron to freeze.

We have referred the question to a distinguished pharmacist, who is of opinion that it would not injure it. (2) Muriate and carbonate of ammonia may be palatably compounded with syrup and strong mint water.

Dr. H. P., of Tenn.—Mr. Dacre Fox has not published any separate work on his treatment of sprains. The extract you refer to was made from a paper before a Medical Society.

Size of Brains.

Dr. N. L. Folsom writes that the brain of D'Arcy McGee, who was assassinated in 1868, weighed fifty-nine ounces.

Student.—Iodine has quite recently been recommended in carbuncle, by Dr. H. L. Snow, an English physician. He paints night and morning around the edge of the anthrax, and covers the whole with a linseed poultice.

MARRIAGES.

MILLER—GAINES.—At Geneseo, Ill. on Thursday, January 20th, by the Rev. Albert Bushnell, Robert W. Miller, M.D., of Guthrie, Iowa, and Miss Lucy A., youngest, daughter of Nelson Gaines, Esq.

DEATHS.

CHAPMAN.—In New York, at the New-York Hotel, Feb. 19, Geo. H. Chapman, M.D.

HART.—In this city, on the morning of the 19th inst., Harry C. Hart, M.D., in the fifty-third year of his age.

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

Trade supplied in Philadelphia by

1215-1267eow **ROBERT SHOEMAKER & CO.**

J. C. BAKER & CO'S
COD-LIVER OIL.

Absolute Purity and Freshness

Secured by Specifying our Brand.

Prepared on the **HALTEN ISLANDS, NORWAY**, with great care, from the finest selected livers of **NET-TAKEN COD FISH**, at a season of the year when they are in their highest condition.
PRIZE MEDAL—PARIS, 1878; BERLIN, 1880

BAKER'S EMULSION

With Hypophosphites of Lime and Soda, containing fifty per cent. Pure Oil, is a perfect and potent preparation.

☞ We employ Baker's Cod-liver Oil in preference to all others. The Pure Oil is palatable and digestible, and the Emulsion is well nigh delightful.

Agents for Barlett's Pile Suppositories.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O	
Quinidia do	15 "	20	24	2	2	
Cinchonidia do	15 "	C	H	N	O	
Cinchonia do	15 "	20	24	2		
Chinoidine Purified,	30 "					

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

TREATMENT OF TYPHOID FEVER IN CHILDREN.

Delivered at Hôpital des Enfants Malades (Paris),

BY M. JULES SIMON,

Physician to the Hospital.

Translated for the Medical and Surgical Reporter.

The treatment of typhoid fever in children differs essentially from the treatment instituted for the adult. No dependence can be placed on active medication, or on any special remedy; a series of indications exist, however, which must receive proper attention.

These may be summed up in the phrase, Sustain the vital forces; excite or calm the nervous system according to the state of the patient; seek to recall the cutaneous functions. During the first days the use, in abundance, of mild emollient drinks, is plainly indicated.

Acidulated drinks are to be preferred, as they are refreshing and most agreeable to take. This will suffice, at first, but after four or five days the administration of alcoholic preparations may be commenced. Alcohol, as you all know, acts as an excitant in certain doses, but on the other hand it is a well established fact that in disease accompanied by high fever it lowers the temperature and sustains the rapidly failing vital forces. The form under which alcohol is administered matters little; brandy, rum, or Madeira wine may be indifferently employed, proper attention being, of course, paid to the dose administered.

During the first period of the malady the child is, as a rule, constipated; but the scene soon changes, intestinal hypersecretion supervenes, and diarrhœa, accompanied in some cases by violent colic. In such cases, emollient fomentations should be applied over the abdomen, and enemata administered, containing two or three drops of laudanum, for a child from five to seven years of age. After two or three days of such treatment, and often sooner, the abdominal pains will become less intense and the meteorism less marked.

Every three days a small dose of some mineral purgative water may be given, not with the object of purging the little patient, but in order to clean out, as it were, the digestive tube.

Every day enemata of water, containing, if desired, some antiseptic substance, may be administered. In order to excite cutaneous secretion, the whole body should be sponged with lukewarm water containing a little aromatic vinegar.

Cold baths should not be employed in the treatment of infantile diseases; moderately warm baths give equally good results, without presenting the dangers of immersion in cold water. The patient should, if possible, be moved from one room to another, morning and evening. The object of this practice is to prevent the prolonged sojourn of the infant in a room where the air is poisoned by the excretions and exhalations engendered during the course of the disease. The most absolute silence, and a darkened room, free from inopportune visitors, will prove of benefit. The diet should be very mild, milk and broths being the staple articles used for the alimentation of the patient.

To sum up, the treatment of ordinary typhoid fever, running its course without notable complications, should consist in directly sustaining the

forces by a milk diet, with broths and alcoholic preparations; and indirectly by diminishing the intestinal secretions and combating the active principle of the disease by washing out the digestive tube, by frequent change of air, etc.

TREATMENT OF COMPLICATIONS.

1. *Abdominal Symptoms.*—When abdominal symptoms are spoken of, super-purgation and intense abdominal pains are generally understood. The absorbents and mild astringents should be employed in such cases; as much as ten grams of creta preparata per diem may be administered in a mucilaginous julep, or four grams of subnitrate of bismuth in sweetened water. Enemata of starch, containing four or five drops of tinct. opii, may be administered; the dose of opium being gradually but cautiously increased.

In conjunction with this treatment emollient poultices should be applied over the abdomen, but the diarrhœa may possibly not be arrested for four or five days.

2. *Thoracic Symptoms.*—The most frequent are generalized bronchitis and congestions of both lungs. Emetics should, in general, be avoided. Ipecacuanha, senega, and the preparations of antimony should not be employed. All these medicaments would but depress the vital forces of the patient, if they did not even destroy him.

Dry cups may be applied over the chest, morning and evening; this is a simple, but powerful, means of revulsion always at the disposal of the physician.

Insist on the alcoholic preparations, which you may prescribe at the dose of twenty or thirty grams per diem, adding, if necessary, a small quantity of extract of quinquina.

If dyspnœa should become very urgent, a flying blister should, without hesitation, be applied on the chest, and should be left about three or four hours in situ, but never more than five or six. Thus applied, it will suffice to produce irritation of the skin; after its removal a large warm cataplasm may be applied, to aid in bringing abont the serous effusion under the epidermis. We should not deprive ourselves of an agent of great power, particularly in children, in the dread of producing an eschar; it is true that this accident happens more frequently in typhoid fever and in cachectic conditions of the system, but its occurrence may always be prevented by removing sufficiently soon the blistering agent.

3. *Cerebral Symptoms.*—These are the symptoms against which therapeutic agents have least power. If the child presents symptoms of great cerebral excitation, chloral may be administered in the dose of one or two grams, or an enema, containing one gram of chloral, one gram of camphor, and the yolk of an egg, may be prescribed. Bromide of potassium should be given only as a last resource, and never for more than two days, consecutively.

4. *Hemorrhage.*—Intestinal hemorrhage during the course of typhoid fever is rare in children; epistaxis is of more frequent occurrence. There is one simple mode of arresting hemorrhage from the nose, which generally proves efficacious. Agaric is cut in long strips, about half an inch in width; these are introduced as deeply as possible, until the nostril is filled; then another is applied transversely across the external opening, and the whole is kept in place by a roller passed around the head. Sometimes it is necessary to saturate the agaric in tincture of ferri perchloridi.

Plugging the posterior nares with the aid of Belloc's instrument should be avoided; it is very difficult of accomplishment, on account of the restlessness of the child; it induces nausea and gives no better results than the other method.

When hemorrhage from the intestine occurs, administer two drops of tr. ferri perchlor. every half hour or every second hour. If this does not suffice, give cold drinks, place compresses wrung out of cold water on the abdomen; internally give pounded ice, which, when mixed with pulverized sugar, is taken without repugnance.

5. *Accidents through Compression.*—Redness and eschars are induced on the parts which support the weight of the body; they appear oftenest on the sacrum. An attempt should be made to prevent these accidents; the pelvis of the child should be supported on an air pillow about two-thirds filled; the parts should be sponged with an infusion of oak leaves, or with some other astringent preparation.

We will conclude with a brief mention of the treatment appropriate to grave forms of typhoid fever.

In *ataxo-adynamic* forms, characterized by delirium with prostration, a blister should be immediately applied to the back of the neck; and when the first has become dry a second may be applied in the same place.

Finally, in *adynamic* forms, in those accompanied by much prostration, tonics and substances acting as stimulants to the nervous system must be insisted on. If necessary, the patient may be plunged into a cold bath; a few seconds' immersion produces remarkable excitation; but this is a means which should be employed only after having in vain tried all the others.

Communications.

ON THE TREATMENT OF NEURALGIA BY STATIC ELECTRICITY.

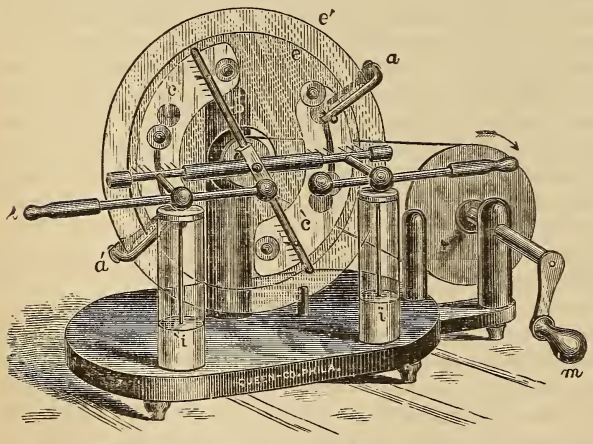
BY WM. R. D. BLACKWOOD, M.D.,
Physician to St. Mary's Hospital, Philadelphia.

The varied list of diseases falling under the care of the profession renders labor and responsibility more or less irksome, according to their gravity; and although acute cases are, as a rule, exceedingly troublesome at times, it is seldom that a critical condition in these instances extends beyond a few days at furthest, or, as generally prevails, a few hours. Chronic affections, on the contrary, from their persistence, are the bane of practice, and none of them present greater difficulty in management than the neuralgias so commonly met to-day in all parts of the land and in all classes of society. An additional matter of note in this connection is found in the fact that while an attack of one or other form of neuralgia is at its height, the patient is, in all respects, in a condition akin to that found in the most acute malady of other types, demanding as much the personal attention of the physician, and even more so, in the majority of instances. This is notably true since the hypodermic system of medication has become universal, and the demand upon the practitioner's time and services has been largely augmented by the inherent necessity of the method, although the reprehensible example has been set by thoughtless members of permitting or encouraging patients to employ the syringe themselves, a fault chargeable with an amount of injury which would hardly be believed by some of these easy-going gentlemen. It is difficult to parallel, for example, the agonizing pain present in the facial neuralgias, notably the epileptiform or central neuralgia of Trousseau, which is almost beyond the ability of human endurance; yet how frequently is this evidenced in the most delicate ladies; and how sad their condition until the paroxysm is absolutely drowned out by morphia; and reflect that the demand for this drug in increasing doses, in time, too often fixes a habit more dangerous than the original disease, and one in itself more baneful, as destroying, in the long run, the mental and bodily health alike, while it may be, at best, only keeping the enemy in check, but not removing it.

Let those who have had a large share of hemicrania, spinal, facial, cervico brachial, intercostal, lumbar, or sciatic neuralgia, revise their cases and determine the percentage of *recoveries*, despite the multitude of specifics of every type, from the oldest to the latest born, with which we are favored from time to time by enterprising manufacturing chemists. It will possibly abash the inquirer (depending somewhat on his temperament to find how many sufferers have wandered from him to his confreres; or in the instance of his regular families, who stick to him through thick and thin, to learn how transient the relief has frequently been, and how often and continuously the patient has required his aid in years gone by. The simple truth about neuralgia is, that the greater part of successful treatment lies in the direction of mitigation, not cure. The reflex neuralgias, such as from decayed teeth, and such like easily removed factors, are, of course, excluded from consideration. It is worth while, therefore, to look further into our therapeutic resources, to learn whether or not during time fruitlessly spent in trial of new remedies, we have not overlooked those which in the past have done good service, but which in the march of fashion in medicine, as in everything else, have been set aside and forgotten. Attention has been called, in the Reporter, by the writer, on several occasions, to the value of the galvanic and faradic currents in nervous diseases, with illustrative cases, and it has been a pleasure to learn, by letter, from far distant members of the profession, that through the interest thus evoked they too have succeeded in frequent examples where before the employment of this invaluable ally their best skill was baffled. With the design of extending the remedial resources of this agent, attention is asked briefly to one form literally unknown to the mass of the profession in its therapeutic aspect—"*Static*," or more correctly speaking, "*frictional*" electricity, the earliest known of all kinds. In a careful examination of twenty works in my library on electro-therapeutics, I find reference made casually in three only, to the use of this variety; yet in a very old manual of chemistry and physics, allusion is made to the great value of "the spark," as it is termed, "in various pains of the bones of the head and the joints, which are thereby cured after all medicaments be of no use."

Now, with sensible men, there is a reason for everything, and having repeatedly observed similar laudations of the "spark" and the "shock" (from the Leyden jar), in several old books in my library, I wondered how the thing was dropped if there was anything in it. Experiment has shown me, during the past half-dozen years, beyond question, that there is a great deal in it, and I can only account for the abandonment of static

electricity because it has heretofore been so difficult to manage, through inherent defects in the old cylinder and plate machines, which worked more or less satisfactorily when you did not care to use them, but which incontinently refused to do anything just as they were most needed. A humid atmosphere or the breath of a small audience has over and over again ruined the exhibition of handsome experiments, to the disgust of more than one lecturer on popular science. The discovery of the Rhumkorf induction coil did away with this discomfort, but as it is not fitted for medical use, faradic and constant currents have sufficed those of the profession who employ electricity in practice. As many neuralgias are worse in wet weather, mechanism unfavorably influenced by humidity is necessarily useless; but, fortunately, this difficulty has been lately completely overcome, and now we have at command apparatus which will under all climatic conditions furnish any desired power, either for therapeutic or experimental purposes. The Bertsch, Holtz and Carrés dielectric machines are all unfavorably affected by humid or muggy weather, even in a warm room; but Messrs. James W. Queen & Co., of Philadelphia, have succeeded in producing a modified "Tœpler" machine, which can be *actually sprayed* with water and yet give a continuous flow or a succession of sparks of high tension as desired. The difficulty thus encountered in a very handsome Holtz machine has been the sole obstacle in the way of my not reporting sooner the value of static electricity in practice, lest similar disappointment might not be borne with equanimity by readers of the Reporter, who might be induced to investigate the matter in the same way that a good number have done in another direction, through my paper, "How to Make a Cheap Galvanic Battery," in the issue of July 31, 1880. As a specimen of fine workmanship and cheapness combined, the "Queen's Tœpler" machine is unequaled, and for efficiency it cannot be too highly commended. The brilliancy of Geissler and spectrum tubes is brought out remarkably by it, and in the way of amusement and instruction in the family circle it will serve a good purpose on many a winter night, especially to those who are debarred from the opportunities of large cities.



The machine illustrated consists of a stationary back plate and a revolving front plate. When put in motion the electricity generated on the revolving plate is taken from the small metallic discs by brushes on the arms *a d* and transferred to the armatures *c c* on the back plate. This plate, when charged, reacts upon the revolving plate by induction, and electricity is taken therefrom by combs on the horizontal cross arms, and passes by spark between the discharging rods *r r*. When the condensers *i i* are removed, the flow is continuous, and of low tension; when they are in position, as represented in the cut, the discharge is in high tension, the sparks being smaller and more rapid, as the sliding rods *r r* are near each other, and slower and denser the greater the separation of the balls. Charges of great intensity can be had through one or more Leyden jars, the potential being regulated by the size and number of jars employed.

In evidence of the advantage of static electricity, the subjoined examples are cited, without unnecessarily going into details:—

Mrs. H. suffered for several years with periodical trifacial neuralgia, which was intensified during menstruation, at which time ovarian neuralgia was usually added. She presented no cause, in the way of imperfect teeth, indigestion, or depraved secretory action, nor did her social position expose her to cold or wet. Quinia, iodoform, belladonna, morphia, and other drugs had been exhausted without other than temporary benefit to the face symptoms and none to the ovarian. She came to me for electrical treatment, and had thorough galvanic applications locally, with general faradization. Although her strength and nutrition was improved the paroxysms were merely shortened when present and somewhat delayed, and after a fair trial I became dissatisfied with the progress which would, doubtless, if persisted in, have ultimately cured her as it has done others, but in view of a trip to Europe I wished, if possible, to finish the case prior to her departure. She came to see me one afternoon when suffering considerably with supra orbital pain. I had been working with my Holtz, rehearsing some experimental illustrations for a lecture, and to amuse her while the constant battery was being set up (it having been discon-

nected for recharging just before she entered) I charged her pretty thoroughly, and drew sparks from the brow and temple for some minutes, with the effect of completely removing the pain before she left the chair. Both constant and induction currents have done the same thing for me repeatedly, with others, but not in her case. She became enamored of the new battery, and I complied with her desire to further test its merits, with the result of permanently relieving her trouble before she left the city. The method employed was to charge her and draw sparks from the affected regions with the knuckles or a wire brush. She had tri-weekly treatment of all applications, but a dozen sittings under static electricity did more for her than treble the amount of the others separately or combined, and she has remained well. Had she not been cured before her European tour, either the voyage or some continental physician would have got the credit, for she was nearer well than I thought at the time the static electricity was used.

Mr. McC., an old patient of mine, had been gradually growing worse, from intercostal pain, laterally over the fifth rib, always constant, but with exacerbations at irregular intervals and usually worse at night. There was no discoverable cause, yet he became daily poorer in weight and general appearance, despite tonics and good feeding. Neither galvanism nor faradism were of service; his only resort was anodynes, but he disliked as much as myself to push them. With the good result of the first case in memory, I got his consent to try the Holtz, although he had no faith whatever in electricity. He got better from the first trial, and in three weeks was a different looking man. In addition to drawing sparks from the seat of pain, which was circumscribed and small in area, I disharged a small Leyden jar at the centre of the painful region, at each sitting, and finished the seance by thoroughly charging him and allowing the charge to gradually escape without drawing it by spark. Two months of treatment relieved him completely, without any assistance from medication. It is true that at long intervals he has slight twinges, but they are momentary, and no painful spot is now discoverable on pressure, as at first. My opinion for some time was that an exostosis existed at some internal point along the rib, which produced the peripheral pain, and that he was therefore incurable, but the result of treatment disproved this idea. He had no syphilitic, gouty or rheumatic diathesis, and I am still at a loss to account for the causation of his suffering. I am inclined, from experience, to attach considerable value to the so-called "positive charge" of Radcliffe in deficient nerve tone, it holding much the same relation as general galvanization or general faradization in bracing up neurasthenic patients.

H. R , a youth of seventeen, who previously enjoyed excellent health, became affected, during the winter of 1879, with neuralgic pain of the left testicle, cord, and perineum. The suffering at times was very great, especially in, as he thought, the lower part of the rectum, which, however, I ascribed to the vesicula seminales, or some point in the cord as it approached the veru montanum. Upon investigation, I was convinced that the trouble arose from masturbation, the semen being prevented from escaping by pressure over the urethra at the anal region, which possibly had produced distention of the duct near its emergence into the urethra. At any rate, he was alarmed at his condition, and relinquished his fault, yet the pain was persistent. He was kept on full doses of the bromides, to allay excitement of the genito urinary tract, and suppositories of belladonna were used at bedtime, with camphor and lupulin. Progress, though present was slow, and after being satisfied of his good faith in avoidance of masturbation, and the suffering being evidently neuralgic, I put him on static electricity without trying either the coil or constant battery, and discontinued the medicine. Improvement was decided from the first, and a couple of months only passed prior to an entire cure. My object in adopting this form of electricity was purely experimental, because, as stated in former papers in the Reporter and other journals, my uniform habit in such cases is to apply galvanism. He has had no return of the pain at any time.

In reporting these cases, selected from a number, I have no desire to deprecate other forms of electricity in neuralgia, or similar phases of nervous disease. My experience with galvanism particularly confirms daily the high position it of necessity occupies when scientifically handled, and although not an unqualified endorser of Duchenne in his estimate of faradism as equal in all respects to galvanism, I know from experience how valuable it is; but my purpose in bringing before the profession the claims of static electricity is simply to do justice to an agent almost forgotten, yet of great value in a wide field, and one which has the additional advantage of being easily manipulated under improved forms of mechanism, agreeable to the patient, safe in its application to points demanding great caution with the pile, and especially in brow neuralgias, in which faradic currents are obnox-

ious to the sufferer and of little utility. Constant batteries are troublesome to maintain, and in the hands of gentlemen not posted in electro-physics rapidly deteriorate, much to their disgust and pecuniary loss; and faradic inductoriums unless well made, don't last forever, the driving cell especially going on a strike at inconvenient moments, particularly with those remote from instrument makers, which is unpleasant, to say the least, to the owners, in the absence of mechanical tact. The static machine, on the contrary, is always easily handled, and as now improved is just as efficient in wet as in dry weather. The cost of frictional machines has heretofore been prohibitive, except to those addicted to philosophical investigation; now it is, so far as needs go in therapeutics, very small, the price ranging from twenty five dollars for a really serviceable apparatus to such higher amount as taste may dictate, in view of its applicability to experiment in the wide and entrancing field which is daily developing the incalculable worth of electricity in every department of life and business, a force once looked upon with awe, as an imponderable and mysterious power, not to be comprehended, but one which, if lost to science now, would leave the world at a loss indeed.

PREDISPOSITION TO AND INTOLERANCE IN DISEASE.

BY J. M. BATTEN, M.D.,
Of Pittsburgh, Pa.

That there is a difference in individuals in predisposition to and tolerance in disease, cannot be questioned. Why is it? This may be answered in the single word *heredity*. Predisposition to and intolerance in disease are twin sisters, hence have been running through the past ages, hand in hand.

Every contemporary human being on the face of the earth has his or her chain, extending back as far as the origin of man. Each of these chains has its respective links, and a cause operating upon any one of these links has its effect upon each succeeding link in the chain. Let each of these links in any chain, commencing with the first, represent the parents (father and mother) of the succeeding link, as their offspring. The latter will represent the second link, and their children the third link, and so on, till the last or contemporary link in the chain is reached. Now, I claim that any cause that has a tendency to decrease vitality, either disease or otherwise, operating on any one of the links in the chain representing the parents has its effect on their children and on their posterity.

Suppose x to represent any link in any y chain, to have been afflicted with any z disease; what is the consequence? Why the predisposition to any z disease in all the succeeding links in the chain is increased to take any z disease, and be less tolerant of the same.

If only father in any x link in any y chain has been afflicted with any z disease, the link representing his children will be less predisposed to and more tolerant in any z disease, than if both father and mother had been afflicted with any z disease. Unless it be their children take the constitution of the mother, in which case they would be less predisposed to and more tolerant in any z disease than the children who take the constitution of the father. It would be *vice versa* the same if the mother had been afflicted with any z disease and not the father. But the children taking the constitution of either parent, in either case, who had not been afflicted with any z disease would be more predisposed to and less tolerant in any z disease than if neither the father nor the mother had been afflicted with any z disease.

If in any x link in any y chain both the father and mother had been afflicted with any z disease, their children would be more predisposed to and less tolerent in any z disease than if only either of the parents had been afflicted with any z disease.

If in any x link in any y chain having been afflicted with any z disease, their children should intermarry in other chains whose links had not been afflicted with any z disease, would their posterity, provided their intermarriage was continued in chains whose links had never been afflicted with any z disease, ever reach a normal predisposition to and normal tolerance in any z disease? This question, I think, can be answered affirmatively provided other causes independent of any z disease did not operate on the chain.

If in case any x link in any y chain had been afflicted with any z disease, would that increase the predisposition to and decrease the tolerance in any other disease in the same link? I think it certainly would. The more links in any y chain that have been afflicted with any z disease or other diseases, the more predisposed to and the less tolerant in any z disease, or any other disease, will be each succeeding link.

If in any y chain none of its links have been afflicted with any z disease, why the contemporary link in the same chain would have a normal predisposition to and a normal tolerance in any z disease, provided none of said links in said

chain had been exposed to causes independent of disease which have a tendency to lower vitality, as dietetic abuses, exposure to cold or wet, want of proper clothing or food, climate or change of climate, overwork, without sufficient rest, living in badly ventilated houses or in cities; for these and causes of a like character must have been, no doubt, among the first in increasing predisposition to and decreasing tolerance in any z disease, and these operating on links in any y chain, either alone or in conjunction with any z disease, will increase predisposition to and decrease tolerance in any z disease, or any other disease, in all succeeding links of the chain.

It is a fact, however, in any z disease of a zymotic nature, that one attack decreases predisposition to and decreases tolerance in a second attack in the same person.

When any z disease is consumption or any other organic disease, it is well known how frequently the predisposition to and intolerance in the disease is transmitted from parent to offspring; and this is only a verification of the scriptural saying, the sins of a father will visit his children, to a third and even a fourth generation. This means, literally, that increased predisposition to and intolerance in disease are transmitted from father to offspring.

It may be claimed that healthy parents often transmit increased predisposition to and decreased tolerance in consumption, and on the other hand consumptive parents transmit a normal predisposition to and a normal tolerance in consumption. In the former case the increased predisposition to and decreased tolerance in consumption are transmitted from the grandparents, and in the latter case, when both parents are consumptive, the normal predisposition to and a normal tolerance in the disease are also transmitted to the children from the grandparents.

The parents of a family of which I know something of the history, were both healthy and lived to old age. Of their children, thirteen in number, six died of consumption. The mother's, brothers and sisters, and her mother, all died of consumption. In this case, the increased predisposition to and decreased tolerance in the disease were transmitted from grandmother on mother's side to grandchildren. Another family; the parents both healthy; father's parents healthy, robust Germans; the mother's sister is partly idiotic and partly paralyzed; of their children, three in number, two are paralyzed and idiotic; one of the latter died recently; the third child seems to be healthy; but none of the children showed symptoms of disease before the end of second year, and as the third child is not that old yet, the probability is that it also will become diseased. I instance another case in which predisposition to and intolerance in disease was transmitted from mother, who died of consumption; the father was a hearty, thick-set Irishman. The daughter was a woman of apparently fine healthy organiz tion. She, after bearing a number of children, died at the end of fourth month of pregnancy; cause of death was not ascertained.

Three young men, about the same age, contracted each a chancre on the glans of the penis, and each followed by secondary syphilis; two of them, after a year's treatment, apparently recovered, the third, is less tolerant of the disease, for the reason that his father contracted syphilis before his marriage, and eventually died from the effects of tertiary syphilis. I might multiply cases in which predisposition to and intolerance in any organic disease are transmitted either through father, through mother, or through both, but the facts are so obvious that it is unnecessary.

With regard to infectious diseases, the facts, as in organic diseases, bearing relation to the transmission of predisposition to and intolerance in disease, may not appear so apparent. The only evidence I can present in relation to the subject are a few observations made by myself.

In the endemic of yellow fever at Newbern, in 1864, there were about one person in two exposed to the same exciting cause took the disease. Among the number attacked, a certain number recovered while the remainder died, notwithstanding treatment and care were the same. This has been true, also, in all endemics and epidemics of yellow fever of which we have a history. The same is true of epidemics of Asiatic cholera, and the same would be true also in epid mics or endemics of variola among the unprotected by vaccination. During the epidemic of variola in 1871–72, many persons came under my observation who escaped the disease altogether, notwithstanding they were exposed to the disease and had never been vaccinated. In not a few persons who were attacked with variola, I noticed that either father or the mother of those attacked had suffered with variola previously. Among those who escaped the disease, I further noticed their parents had never been attacked with any disease. Upon inquiring into the history of those who died, I found that their parents had either had variola previously, or had been afflicted with other diseases. I believe the same may be said of scarlet fever, measles, diphtheria, or typhoid fever.

How often is it noticed in families living in the same neighborhood, on the same street, and even in the same block of houses, the sanitary conditions of which are apparently the same, when an endemic of scarlet fever, diphtheria or typhoid fever visits the location named, some one of the families have all or a portion of their children attacked with the disease, some of which die, others recover, while other families in the location named escape the disease altogether. Of course, it may be said that all these families or the different members of the same family, may not have been exposed to the same exciting cause. And this may be true very frequently, but is it not also true, that predisposition to and intolerance in disease, which I believe is transmissible, forms, very often, the very important factor in the cause of disease and death.

There are many families who have come under my observation and who, amidst disease of all kinds and death all round them, have escaped them all. If we acquaint ourselves with the history of these families' ancestry we will find either that they had a normal predisposition to and a normal tolerance in disease or were approximating them.

And in conclusion I would say, if it were not that every birth is a regeneration, and were the constitutional predisposition to and intolerance in disease which diseased parents transmit to their offspring not modified by an inalienable bequest of the older world and by the redeeming instincts which our all-mother grants to every new-born child on earth, the people of the world would long ere this have become extinct.

STONE IN THE BLADDER OF A FEMALE REMOVED BY LITHOTRITY.

BY H. O. SPENCER, M.D.,
Of Erie, Pennsylvania.

In the month of June last I was consulted by Mrs. C., of this city, who brought her daughter Mary, aged twenty-six years, single, to my office, for examination and treatment. She informed me that the young lady had been troubled with some "female difficulty," as she expressed it, and had been treated by a number of physicians, for leucorrhœa, prolapsus uteri, etc., but had received no benefit, in fact, was getting worse all the time, and that her sufferings were becoming unendurable, especially when she attempted to urinate; said that something "stuck" her in the region of the bladder, so that she could not keep from crying out. I made a thorough examination of her case, and came to the conclusion that there must be stone in the bladder. I attempted to introduce a catheter, but the urethra was so irritable that I found it impossible, unless I should administer an anæsthetic, which I did not like to do, thinking it would be better to give her an anodyne, with diuretics, and wait for results.

This treatment had a very favorable effect, and she improved in her general health and appearance, but still had difficulty in voiding her urine. She went along in this way, passing the summer quite comfortably, until the twentieth day of September. I was summoned in great haste to see my patient. I found her suffering terribly. I could hear her screaming before I got to the house, and when I entered her room I found her mother and sister crying, and with the trio was Father C., the priest, giving all the assistance and consolation in his power. I soon learned that she had attempted to urinate, and all at once the water stopped, and that "something stuck her again," as she expressed it.

I at once proceeded to introduce a silver catheter, but before it entered the bladder I felt it come in contact with a stone. Having a very slim pair of polypus forceps with me, I introduced them into the urethra and had very little trouble in getting hold of the stone, which was about the size of a hickory nut, and which I removed in a few minutes by careful and gentle traction. I then gave my patient a dose of morphia, hypodermically, and in a short time had the pleasure of seeing this suffering girl resting sweetly. From this time on she improved rapidly, and expressed herself as being cured, for which she and her friends expressed great thanks to me. Everything went along smoothly with her, and I heard nothing from the case until the twentieth day of December. Her mother called and informed me that Mary had the same difficulty again in urinating, and that she felt confident there was another stone. I informed Mrs. C., that I would call in the afternoon. I did so, and at once proceeded to introduce a sound. As soon as the instrument entered the bladder I felt it "click" against the stone, and by a little manipulation I soon learned that instead of being small, like the one first removed—the size of a hickory nut—it was as large as an ordinary hen's egg. I informed the anxious mother that the stone was too large to be removed without first dilating the passage, and set myself to work to do it, by first introducing a small bougie, and the next day a larger one, always having them well smeared with ungt. belladonna. In a few days I thought I had suffi-

cient dilatation to remove the stone; introducing my forceps I seized it, but soon found that it was too large to remove whole, unless I used the knife, which I did not like to do if I could avoid it. I determined to crush it and take it away in pieces. I then introduced an instrument for that purpose and soon had the stone in at least four pieces, which I removed separately in a short time. I then washed out the bladder thoroughly, which brought away several small pieces. I then administered an opiate and left my patient for the night. I learned in the morning that she rested well, and the day following was sitting up. She has been gaining rapidly, and says "she is cured this time, sure." Being of the opinion that it is a very rare thing to see a case of stone in a female, I thought it might be well to report the case.

Hospital Reports.

BELLEVUE HOSPITAL, NEW YORK.

CLINIC OF FRANCIS DELAFIELD, M.D.,

Adjunct Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons, N. Y.

Reported for the MED. AND SURG. REPORTER.

Organic Heart Disease, with Parenchymatous Inflammation of the Kidney.

GENTLEMEN:—This is a boy, fourteen years old, who was admitted to the hospital on the 8th of December. Five years ago he had an attack of chorea, which lasted for three years. Three years ago he had an attack of rheumatism. During the summer of 1879 he began to have pain in the left side, shortness of breath and palpitation. At about the same time he began to cough, and he has continued to cough ever since. He has had some hæmoptysis and night sweats. During the winter of 1879 it was noticed that his feet and legs were swollen, and his face also. That was the first time at which he began to have dropsy. And at that time he passed only a small amount of urine, suffered from severe headache, and from vomiting. There has been no trouble with his sight. The dropsy which came on during the winter of 1879 lasted for an unknown period and then disappeared, and this winter, some time before he came in, on the 8th of December, the dropsy again returned.

At the time that he was admitted to the hospital physical examination showed a mitral regurgitant murmur of the heart, with hypertrophy and dilatation of the left ventricle. His urine contained albumen; contained no casts; and the specific gravity was 1.020. The amount of urine since he has been in the hospital has varied from twenty ounces up to eighty ounces. Twenty ounces was the smallest amount, eighty ounces the largest amount. It has been gradually increasing since he has been in the hospital, and he ordinarily passes from fifty to seventy ounces of urine a day at the present time. The dropsy has also improved since he has been in the hospital.

This is some of his urine, which you will observe is of about a natural color, a little dark. The specific gravity has been about 1.020 most of the time. When we add nitric acid in the ordinary manner you see that there is a considerable deposit of albumen, but still the quantity is not nearly as great as we sometimes get.

Here, then, we have a boy, fourteen years old, who had rheumatism in 1878, shortness of breath and palpitation in the summer of 1879, who had dropsy in the winter of 1879, a dropsy which lasted during part of the winter and then disappeared, and at the time he had the dropsy he also suffered from headache and vomiting. This winter, in December, the dropsy came on again. Since he has been under observation, since the 8th of December, it is evident that he has organic heart disease, that he has hypertrophy and dilatation of the left ventricle, with insufficiency of the mitral valve. His urine has been of a specific gravity of about 1.020, it contains a considerable amount of albumen but no casts, and although it was a little scanty when he first came into the hospital, since then it has been in excess of the normal amount. The dropsy since he has come into the hospital has in great measure disappeared. You observe that at the present time he has not much dropsy.

Well, of course, anybody would say the boy is suffering from organic heart disease and Bright's disease. But that is not being specific enough. The question is, what is the condition of the kidney? As regards the condition of the heart we can be tolerably certain; he has insufficiency of the mitral valve, and he has hypertrophy with dilatation of the left ventricle, as a result, probably, of the attack of rheumatism from which he suffered some years ago. But, in addition to this, he has given us the symptoms of a renal disease, and those symptoms have been, dropsy coming on a year ago; at that time not only dropsy but vomiting and headache, and at that time the urine diminished in amount. We do not know anything about the urine at that time, except that it was diminished in amount. These symptoms disappeared, but they came on again this winter; and this winter he again had dropsy, which is now getting better; his urine was again scanty for a time, but is now in excess; and his urine since he has been in the hospital has been of a specific gravity of about 1.020, and has shown a considerable amount of albumen, but no casts. Now, what sort of kidneys has he? "He had a tubular nephritis at first, I presume, and now an interstitial." Well, why would you think it has changed from a tubular to an interstitial nephritis? "From the fact that there are no casts in the urine at the present time. As a usual thing, in case of tubular nephritis, I would suppose there would be granular and fatty casts at this time." Well, I cannot find fault with you for saying that, because that is a thing which is very generally taught; but I believe the fact to be just the opposite; that in the majority of cases in which the disease is confined to the epithelium of the tubes, in which it is properly speaking a tubular nephritis, those are just the cases in which you do not get casts; and that the cases in which the interstitial tissue is involved are just the cases in which you do get casts.

Of course, that is in opposition to what is ordinarily taught, so that I cannot find fault with you for the opinion which you have given. Of course, there is a difference in the reasoning, for we do not know whether or not when he had his dropsy, a year ago, there were casts. Of course, reasoning as you do, you would suppose there were; reasoning as I do, I should suppose there were not. I should agree with you, however, that he had suffered from what may be called tubular nephritis, meaning by that an affection of the kidneys in which the lesion is confined to the epithelium of the tubes and the epithelium of the malpighian bodies, without any affection either of the stroma of the kidney or of the malpighian tuft. I should believe that that was the disease from which he began to suffer, but I should also believe that it was the disease from which he is still suffering. The specific gravity is still high. You will observe that although he passes a considerable amount of urine, more than the normal amount, yet the specific gravity continues to be 1.020, which is near enough to normal when the amount is normal. If he had been developing interstitial changes in addition to the changes in the tubes, in other words, if he had gone on to have chronic diffuse nephritis, the specific gravity would not be likely to have continued at what it is now. Then, although it is a smaller thing to go by, the appearance of the urine is of some consequence in these cases. A patient who is suffering from chronic diffuse nephritis, that is, from changes both in the epithelium of the tubes and in the stroma of the kidneys, does not usually have urine of that color. He has a light, pale-colored urine.

Then, the absence of casts which exist at the present time would be to me a confirmation of the theory that he is suffering simply from an affection of the tubules of the kidneys, and not of the interstitial tissue. When I say this, however, I must say a little more exactly what I mean. If a patient have that form of kidney disease in which the principal changes are in the interstitial tissue, but comparatively few changes in the tubules, such a patient will have but very few casts in the urine; there may be so few that you will hardly discover them at all. Not only will there be few casts, but there will be very little albumen. The albumen will be absent just as the casts are absent. When you have at the same time a large amount of albumen persisting, and a small number of casts persisting, with high specific gravity of the urine, and with urine of such a color as you have there, and with the rest of the history to match, the probabilities are that the patient is suffering from that form of kidney disease in which the epithelium of the tubules and of the malpighian capsules alone is involved. That I should believe to be the condition of the boy at the present time: that he is suffering from organic heart disease; that he is suffering at the same time from parenchymatous inflammation of the kidney, using the term parenchymatous inflammation in its strict sense.

Now, as to the prognosis and the treatment. The prognosis, I am sorry to say, is not very good. It is made much worse by the cardiac complication. If it were not for this it would be possible for him to get well; it would be possible for the renal trouble to gradually disappear and not come back; but the cardiac complication makes this much less likely.

Then, as to the treatment. The treatment is, to a certain extent, a palliative one. Since the boy has been in the hospital he has had enough to eat; he has been in a place that is warm, almost too warm; he has been taking diuretics, and his dropsy has gradually diminished. The heart's action has become more regular, and the general condition of the boy has improved, and I should hope that his experience this winter will be the same as it was last winter; that the dropsy will disappear altogether, that the boy will feel better, and that he will be well during the spring and summer. But next winter the same thing will probably recur, and we will have the same story of dropsy over again.

Chronic Diffuse Nephritis.

Case 2.—This is a man, fifty-eight years old, who was admitted to the hospital on the 15th of January. He says he was in good health until about two months ago. He has always been intemperate, and for some time past he has been very intemperate. He has had slight cough for some years. About six weeks before his admission to the hospital his legs and feet began to swell, and there was also some œdema of the face. There is now œdema of the legs and hands, and of the arms. He has had a good deal of headache during the past six weeks and some difficulty of vision. There is also a history of constitutional syphilis. At the time of his admission to the hospital his urine was alkaline; it was of a specific gravity of 1.014; it contained albumen, but no casts were found. The quantity of urine was in excess at the time of his admission. He was passing sixty ounces on the first day, and since then he has been passing between sixty and eighty-five ounces. This is his urine. Now, you will observe the difference in color between these two. The urine from this man is turbid, it is not a clear urine, and that turbidity changes its color somewhat. The other urine, that of the boy, is perfectly clear; and if you were to try and abstract the turbidity from this man's urine you would observe that it would be a great deal paler urine than this other, which is perfectly clear. This urine of the boy, although it is perfectly clear, has considerable color. Here, again, we have albumen, but we do not have it to the extent that we had it in the former patient's urine. It is present in fair quantity, but it is not present to anything like the amount we had in the last case.

Well, now, we have a man who has always been intemperate, who has had constitutional syphilis, who is now fifty-eight years old, and who says that he was not ill until two months ago. I confess I should not believe that. I should not believe he had been well until two months ago, no matter what he said. But his history is, that he was well until two months ago, and that six weeks before his admission he began to have dropsy, and that dropsy has continued up to the present time. At the time of his admission to the hospital, six weeks after the commencement of the dropsy, his urine was of a specific gravity of 1.014. It contained the amount of albumen

which you see; it contained no casts or very few casts. When we say no casts we generally mean very few casts. The urine was in excess. The dropsy has diminished since he came into the hospital. A few days ago, when I saw him, the dropsy was marked, but now it has in great measure disappeared. You can observe he has a pretty well marked syphilitic eruption on the arm.

Now the question is, what sort of kidneys has this man? Here again you would say that the man has Bright's disease, and you would say very correctly. But the question is what sort of kidneys has he? What is the anatomical lesion? "It may be interstitial, it may be a waxy kidney." Yes, he might very well be suffering from what are called waxy kidneys. When we say the man has waxy kidneys, however, we ought to be a little more definite as to what we mean by that. What do you mean when you say a man has waxy kidneys? "A kidney in which degeneration began in the walls of the blood vessels, by a deposit of a waxy material." You mean, then, there is an infiltration of the so-called waxy material in the walls of the blood vessels, and especially of the malpighian tufts. Is that all the matter with the kidneys? "After awhile the tubules also become degenerated, and then the interstitial substance itself, in the same way." Well, there again you speak as you are taught, but you speak as I should not agree with you. That is, I should not agree with you as to the sequence of the change. It is very commonly taught and very commonly believed, that in waxy kidneys the first change is in the walls of the arteries, and that the changes in the tubes and interstitial tissue come on secondary to this, and after this. This I believe is not so; and the reason that I believe thus is, that in the very earliest examples of waxy kidney that you can possibly meet with you can find the changes in the tubes and in the stroma already advanced, and you will find them more advanced than the changes in the walls of the blood vessels. You can, for example, meet with kidneys having the gross appearance of the large white kidney, with very marked changes in the tubules, with very marked changes in the interstitial tissue, and yet with a waxy infiltration just beginning in a few of the loops of the capillary tufts and malpighian bodies. And this is the rule, and not the exception, as I believe. I believe the rule is, that the changes in the tubules and stroma are developed sooner than the changes in the walls of the blood vessels.

When we say, then, that this man has waxy kidneys we mean really that he is suffering from chronic diffuse nephritis with waxy infiltration of the walls of the blood vessels added to this; that he is suffering from ordinary chronic diffuse nephritis, and to the lesions of chronic diffuse nephritis are added waxy infiltration of the walls of the blood vessels. That I believe is the sort of kidney that he would be likely to be suffering from. These kidneys would appear to the naked eye what are ordinarily called large white kidneys; the form of kidneys in which the two kidneys would weigh from sixteen to twenty ounces. The cortex would be thick and white, and the pyramids would be large and red. And if we examined them minutely we would find well marked changes in the tubes, patches of new connective tissue in the cortex, and we would find more or less waxy infiltration in the malpighian bodies, and perhaps in the small arteries. The specific gravity in this man, although it is lower than it should be, is not as low as it is in those cases in which waxy infiltration is far advanced. That is the general rule. If you have a case in which the waxy infiltration is very far advanced indeed, the specific gravity runs down usually lower than this, to 1.010 or 1.009; sometimes it will even come down to 1.002 or 1.001. So, although one cannot be absolutely certain, still I should think the probabilities were, that, although there is waxy infiltration in this man's case, it is not very far advanced; that it is one of the ordinary cases in which lesions of the tubules and of the stroma are much more advanced than is the waxy infiltration.

Now, what is the prognosis and the treatment in this case? Here the prognosis is certain, and it is certain only in one way. It is certain that the man will never entirely recover from his kidney disease. When this sort of kidney has once begun it is something that never disappears. When a man has it he always has it. The symptoms may develop with more or less rapidity; some patients go on for a number of years, having symptoms from time to time, being pretty well the rest of the time; in other patients the symptoms become well developed much more quickly.

Then, as to the treatment. This man has not been taking anything. He has simply been kept quiet since in the hospital, quiet in bed. and absence of alcoholic drinks has been sufficient to cause the dropsy to disappear. He has taken no diuretics. He has taken no cathartics. The dropsy has just gone away of itself. That is a thing we see commonly enough in the hospital, and we see it, not because the men live so extraordinarily well after they come into the hospital, but because they had been living so very badly indeed before they came into the hospital. This man has done about as well as he could do. The dropsy has gone away, his general condition has improved, and that is about all we can expect. In the course of a moderate length of time he will probably be well enough to go away, and go about his business again, and then how quickly the symptoms will return will depend very much, I suppose, upon how much he drinks. If he begins to drink hard again the dropsy will probably come on again pretty soon; if he be more moderate in his drinking, the dropsy may leave him alone some little time, especially if he can go through the winter until warm weather.

Case 3.—This man is forty-eight years old; was admitted to the hospital on the sixteenth of January. He says he was in good health until about a year ago. He has been intemperate for a good many years. For the past year he has had a constant cough, has had pain in the chest, most marked in the right side, and night sweats. He has never had hæmoptysis. He has lost about forty pounds in weight. Physical examination shows signs of a cavity on the right side, and of consolidation at the left apex. About one month ago his feet began to swell, and they

have been swollen ever since. The legs have become œdematous, and there has been some œdema of the face. There has been some loss of vision. He has never had much headache or vomiting. His urine is of a specific gravity of 1.020. It contains albumen. And here again no casts are to be found. The amount of urine passed on the sixteenth of January was twenty ounces; on the seventeenth, forty ounces; so it has been increasing since he has been in the hospital. This again is pale, but somewhat turbid urine. And here again we have a considerable amount of albumen.

We have, then, a man, forty-eight years old, who has had marked pulmonary disease for a year or more; who has marked lesions in the lungs resulting from that; and who has developed renal symptoms within about a month, the renal symptoms consisting in a dropsy involving the feet, the legs, and the face; a diminution in the amount of urine; a diminution which has disappeared, as he now passes forty ounces, the urine being of a specific gravity of 1.020, and containing, as you see, a considerable amount of albumen, and being said to contain no casts. His œdema, again, has diminished since he has been in the hospital. There is now a little œdema of the feet, but there is not much.

Now, here again is a man who has Bright's disease. And here again the question comes up, what sort of Bright's disease has he? What is the anatomical condition of the kidney? Well, this particular case is a case in which it is not fair to ask any of you to give an opinion, because it is a sort of case in which the symptoms might mislead you. In judging in these cases of the kidney disease, we have two sets of data to go by; we have to put together what we observe during life and after death. We have a comparison of the general history and of the condition of the urine during life with the condition of the kidneys after death. This is one way in which we judge as to the condition in which the kidneys are during the life of the patient. But then, besides this, there is another sort of experience in kidney disease, and that is, that patients who develop kidney disease in a certain way, under certain circumstances, are pretty sure to have one kind of kidney disease, no matter what the condition of the urine and no matter what the clinical symptoms may be. You will observe here is a sort of contradiction, but it is a contradiction which is founded on fact. Now, you will observe that the history of the urine of this man is such as would warrant you in saying that he has the same sort of kidney trouble as the boy has who first came in; that he has a tubular nephritis. You will remember that his urine at first was diminished in amount, but it is now passed in normal quantity; he has urine of about normal specific gravity, 1.020; it contains albumen, no casts, and the symptoms have lasted only about a month. That sort of history, under other circumstances, would warrant you in that diagnosis; it would warrant you in saying that the man was suffering from parenchymatous nephritis, or tubular nephritis, whichever you choose to call it. But that history is not the whole of the history of this man. This man, in the first place, has been in the habit of drinking; I will not say he has been intemperate, but he has been in the habit of drinking for a number of years; he has had a chronic pulmonary disease for the last year, and it is now well marked.

Well, as a matter of experience, when we have renal symptoms developing in such a patient as this the sort of kidney lesion that we have is not tubular nephritis, or parenchymatous nephritis, but chronic diffuse nephritis. A lesion of the kidneys in which both the tubes and the stroma, and very often the malpighian bodies also are involved. It is perfectly possible that in this man there may be waxy infiltration of the malpighian bodies. I do not know that there is. There might be and there might not be. But I can say that there are already well marked changes both in the tubules and in the interstitial tissue. In this case, again, it is not worth while to try to say whether the patient has large white kidney or whether he has contracted kidney, or whether he has one of those kidneys which is neither enlarged white kidney nor the contracted kidney. If you take a case with the whole history of this man you cannot be certain that he has the large white kidney. It may turn out you are correct, but you are correct by a guess, that is all; the next patient with the same history might have the contracted kidney, and the next patient neither enlarged white kidney nor contracted kidney; but you can be sure such patients are suffering from chronic diffuse nephritis, a lesion in which both tubules and stroma are involved. You cannot be sure as to whether there is added to this waxy infiltration of the malpighian bodies.

You can be sure as to the prognosis. It is bad. This, however, is a matter of less consequence in this case, because you have already another disease of which the prognosis is equally bad. The phthisis has already so far advanced that there can be little question as to the ultimate result, so that the kidney lesion will merely add to the other symptoms.

Tænia in the Human Subject in Denmark.

Dr. E. Krabbe, in 1869, communicated the particulars of 100 cases of tænia observed by himself and Professor Hannover, in Denmark, and he has since examined 100 more cases in the same country. Of the 200 cases rather more than half belonged to the city of Copenhagen, and the number was much larger in women than in men. The relative proportion of the different kinds of tænia has lately exhibited some remarkable modifications, especially as regards the *T. mediocanellata* and the *T. solium*, the former having been much more frequently observed since the year 1869. Dr. Krabbe (*Nordiskt Medicinskt Arkiv*, vol. xii, 1880) accounts for this result by the terror of the trichina which has prevailed since 1865, and has led to an extreme prudence among the population in the consumption of raw pork. On the other hand, this prudence has not extended to raw beef, and it is too little known that this kind of meat may also contain cysticerci. Raw scraped beef has been frequently recommended by physicians as a dietetic remedy for children and persons prostrated by debility.

Periscope.

The Etiology of Vertigo.

At a meeting of the Medico-Chirurgical Society of Edinburgh, in January, Mr. McBride read a paper on the etiology of vertigo, of which the following is an abstract: In relation to this subject the theory was advanced that a nerve impulse striking the brain may, according to its intensity, involve a large or small central area. For instance, the pain caused by a carious tooth might be confined to those fibres of the fifth nerve corresponding to the tooth, or the impulse communicated along these fibrils might overflow and involve the central terminations of other fibrils, and even other nerves, producing earache, faceache, and mastodynia. It was, therefore, urged that nerve impulse communicated along any one nerve may overflow and involve other brain areas. Shock was considered to be an overflow of nerve impulse so powerful as to involve centres necessary for life. It was argued that vertigo is a definite sensation, and that for any sensation to be experienced a definite encephalic tract must become active. From experiments on animals, the effects of rotation in the human subject, and the phenomena of Menière's disease, it is known that stimulation of the nerves of the semicircular canals produces vertigo, and that therefore their central terminations must be in close relation with a vertiginous centre, which may (at least physiologically) be assumed to exist. We know, further, that irritation of the canals, if severe, is apt to cause vomiting, syncope, nystagmus, and other phenomena. It is therefore probable that nerve impulse communicated to the vertiginous centre tends to overflow and involve other centres (*e. g.*, the vomiting, cardiac, inhibitory, and oculo-motor centres). Probably all of these centres are in physiological relation (the central termination of the nerves of the semicircular canals, the vomiting, and the oculo-motor, as also the cardiac inhibitory); therefore impulses communicated to one tend to overflow to the others. In some persons it is justifiable to assume that a nerve impulse tends to overflow more readily on account of unstable equilibrium of the nerve centres, or perhaps of particular nerve centres. Nerve impulse also seems to spread in a definite physiological direction, as seen in the constant results of accidental or experimental lesions of the semicircular canals in man and the lower animals. Possibly this line of argument may be applied to the so-called explosive neuroses. If it be once admitted that vertigo may be produced by impulse applied to the oculo-motor centre, we have here an explanation of those cases where vertiginous phenomena are produced in animals after section of both auditory nerves. Vertigo may originate from causes (1) visceral, (2) ocular, (3) aural, as well as central (epilepsy, etc.) and general (anæmia, etc.) causes, as also through nerves of common sensation (pain). The general conclusions arrived at were—

1. That there is a cerebral area or tract, stimulation of which produces vertigo.
2. That this area may be stimulated by impressions ocular, auditory, sensory, or visceral, as well as central changes, and is in intimate physiological relation with the vomiting and oculo-motor centres. That is to say, impressions conveyed to one of those centres tend to involve the others by overflow of nerve energy.
3. That excessive stimulation of the vertiginous area will produce an overflow of nerve impulse to various motor centres, and probably unconsciousness.
4. That inasmuch as the phenomena of its excessive stimulation (as in rotated men or animals, Menière's disease, etc.,) are represented by a definite train of symptoms, we may infer that overflow of nerve impulse usually proceeds in the same direction—in other words, involves the same centres—first those which are intimately connected with it, then those more remote.
5. That possibly the same process of reasoning may be applied to death from shock, epileptic attacks, convulsions, and some of the other so-called explosive neuroses.
6. That in typical cases, ocular, stomach, and auditory vertigo may be distinguished from one another by the centre first involved. Thus we should expect that stomach vertigo would be preceded by nausea, if not vomiting; that ocular vertigo would be caused by changes in the motor apparatus of the eyeball, but that in auditory vertigo the giddiness is the first and may be the only symptom.
7. That sea-sickness is probably generally due to stomach irritation. for here, as a rule, we have first vomiting, and afterwards vertigo, which is, however, by no means a constant accompaniment.

Treatment of Wounds by Immersion.

Dr. C. B. Hutchins, of San Francisco, writes, in the *Western Lancet*:—

Reading, in a Cincinnati medical journal, with regard to the treatment of wounds and injuries by immersion, reminds me of a case which came to St. Luke's Hospital about five years since. It was that of a man who was engaged in loading wood on a railroad car; the wood being on one side caused the car to tip so as to allow the wood to slide off, when the car fell back to its position on the track; but in falling it caught the arm of one of the laborers between the wheel and the track, causing a double compound fracture of both bones of the left forearm. At both ends of the fracture the bones were uncovered. The accident took place in Marin county, and it was two or three days after the injury before the dressings were applied.

A tin receptacle was made by the tinsmith, which would allow the forearm to lie on the bottom, and the arm was kept covered with a solution of boracic acid. The arm had become enormously swollen, and the temperature of the fluid was so much increased that it was necessary to

keep ice in the fluid for some days. This was the whole treatment. There was not a tablespoonful of pus escaped from the wounds. The arm, while being a little deformed, was as useful as before the receipt of the injury. No report was made at the time, from the hope that another case might occur in which the treatment could be again tried. The solution was renewed about every three days at first, and then at longer intervals.

Treatment of Indigestion and Heartburn.

In the course of an article in the *Practitioner*, January, 1881, Dr. J. Milner Fothergill writes:—

For the purpose of whetting the appetite and thus acting reflexly upon the gastric secretion, we employ the class of agents known as bitters. To these we add hydrochloric acid. Ringer has pointed out how an alkali taken into the stomach before a meal, when the stomach is alkaline, produces a freer flow of acid afterwards. Consequently we comprehend the value of that well-known preparation indifferently termed, "Haust. Stomach," or "Mist. Mirabilis," or "Mist. Rhei et Gentian," in the various hospitals; a combination of world-wide fame. One drawback to this combination of rhubarb, gentian and soda is, that the student becomes familiar with it and its virtues, but remains ignorant of its exact composition, and so loses sight of it when he enters upon practice for himself. Such a mixture before meals, followed by ten drops of hydrochloric acid after the meal, will often make the difference betwixt imperfect digestion, producing discomfort, and digestion so perfect that it does not provoke consciousness. Or where there is much irritability in the stomach, *i. e.* when a bare, red tongue imperfectly covered with epithelium suggests a like condition of the internal coat of the stomach, then bismuth is most soothing. The mixture of soda, bismuth, and calcimba is in use for such indigestion with good results. The dietary in such a case should consist of the blandest food, milk, with or without baked flour in it, beef tea with baked flour; nothing more till an improved condition of the tongue tells of a more normal condition of the stomach. In such cases a plain opium pill at bedtime often soothes the stomach very nicely. Then there are cases where imperfect digestion is accompanied by the production of fatty acids, butyric and others, which add the phenomenon of "heartburn" to the symptoms; or there may be later products formed which cause the bitter, hot taste in the mouth on awakening in the morning or after a post-prandial nap. It is usual to treat "heartburn" by the exhibition of an alkali; but this is not good practice. In union with an alkali the offending matter is nearly as objectionable as in the form of free acid. It is much better to give a mineral acid, as the hydrochloric, or phosphoric, which breaks up the feebler organic acid. By such means we can aid the digestive act. Then at other times the indigestion is due to lithiasis, where the presence of uric acid impairs the efficiency of the gastric juice. In these cases all measures which do not entertain the causal relations of the dyspepsia are of little use. By the administration of potash in a bitter infusion, well diluted, taken half an hour before a meal, this element of trouble is removed. In all cases of gouty persons suffering from dyspepsia, do not forget this cause of impairment of the gastric juice.

Treatment of Carbuncle by Carbolic Acid.

In the Toledo *Medical and Surgical Journal*, Dec., 1880, Dr. J. T. Woods writes:—

It is now about two and a half years since a patient presented with two carbuncles, one on the back of the head, the other below it, on the neck. They were of moderate size only, the upper one open in three places, while in the lowest the skin was unbroken.

Having considered the various known properties of the carbolic acid, I determined to use it vigorously instead of inserting it in meagre quantity. I loaded my hypodermic syringe, and passing the point through the openings and into the sloughing mass in every direction, I completely saturated it with the pure acid and awaited results. In a minute the smarting disappeared and with it all pain and all sense of soreness.

By this result emboldened, I again charged my instrument, and thrusting it through the skin over the other carbuncle, in a variety of places, I soaked the whole carbunculous mass beneath the skin, enough of necessity escaping to fully bathe the borders, modify inflammation and destroy any septic elements then developed. I waited, not without concern, and was delighted to learn in a few moments that all the pain and soreness was gone in this also. The skin over the mass became quickly white, hard and dead, and in a few days detached, in the form of a slough, the interior mass also becoming rapidly loosened, only requiring the cutting of a few shreds to remove it, when the cavity was found to present a satisfactory appearance and rapidly filled up, leaving an exceedingly small cicatrice. The remarkable feature in this case was that after the complete saturation of the carbunculous mass no pain occurred, my patient going about his ordinary labor without discomfort. It is now one year since I treated a very painful case, the same method bringing about similar results, the party suffering no pain or even soreness after the lapse of one minute following the injection.

In making this suggestion, which so far as I know is new, I am conscious of the insufficiency of my cases, but I am so sure of its efficacy that I shall at once resort to it when case and occasion offer, and advise others to do so, at least until the value of the measure is determined.

In conclusion, I would advise the use of the pure acid only, and to complete saturation. Dilution would increase, if not create, danger of absorption of the acid, converting a very simple procedure into a condition of great danger, and insufficient quantity defeat the purpose for which it is used.

Remarks on the Treatment of Neuralgia.

Dr. W. C. Boteler writes, in the *Maryland Medical Journal*, Jan. 11:—

In looking for a treatment of neuralgia, I confess that I entertain the greatest respect for per-

sonal experience. The most diversified and even opposite modes of treatment frequently give good results. It is, of course, of paramount importance to search for the cause of the neuralgia, but unfortunately the most pains-taking inquiry is often unsatisfactory, and then our only resort is to attend to the symptomatic pain. This justifies a successive trial of reputed remedies, which include a large number of empirical ones. Nevertheless, it may be truly said of neuralgia, that of all the disorders of the nerves system, its prognosis is the most hopeful. If we are not uncommonly baffled to effect a permanent cure, we can at least alleviate the suffering of the patient at all times, and this may be speedily accomplished by the judicious hypodermic administration of morphia. I am convinced that even a perfect recovery from neuralgia not seldom follows the adoption of this therapeutic measure. A wide field for the application of our remedial resources is offered by the indications of treatment which the general condition of the patients suggest. Those who have observed the disappearance of even inveterate neuralgic disorders under the influence of a tonic, supporting and recuperative treatment cannot doubt the efficacy of such a procedure.

Antiseptic Removal of Scrotal Elephantiasis.

The antiseptic method in this operation is recommended by Dr. M'Leod, in the Edinburgh *Medical Journal*, Feb., 1881. He says, at the conclusion of his article:—

To sum up, the advantages which appear to me to result from the strict antiseptic treatment of these cases are: 1. By stitching the testes in place they are prevented, however long the cords, from being floated downwards or forwards by the profuse discharge. Less lymph suffices for repair, and the process of convalescence is thus materially shortened and final recovery accelerated. 2. The process of inflammation is entirely prevented. Repair takes place by physiological process, without intervention of any pathological phenomenon. 3. No constitutional disturbance takes place except the primary or reactive fever, which ensues within the first forty-eight hours, and this is very mild. 4. The risk of septic infection is entirely removed. 5. The process of dressing is painless, owing to absence of inflammation. 6. The patient is not a source of offence to himself or of danger to his fellows, putrefaction being entirely averted. 7. Cicatrization is materially accelerated. 8. The penis can be more easily kept free—a matter of considerable importance. 9. Much suffering and discomfort are avoided. 10. The risk of death is reduced.

—In New York City the total number of deaths reported up to noon, February 26th, from January 1st, was 6348, an enormous increase over the record of previous years. This is an average daily death-rate of 111 in the week of six working days. It is thought the increased population, the severity of the weather, and the prevalence of epidemic diseases have something to do with the increase, which would make this year's record reach or exceed 38,000, while that of 1880 was only 31,000.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The Newark Eye and Ear Infirmary, under the care of Dr. C. J. Kipp, has issued its first annual report.

——A neat reprint is a lecture on the clinical anatomy of the lower extremity, and especially of the knee and ankle joints, by Dr. W. W. Keen, of this city.

——The Report of the Committee on Obstetrics of the Illinois State Medical Society may be had in reprint form from the chairman, Dr. G. W. Nesbitt, Sycamore, Illinois.

——An interesting sketch of Dr. Edward Jenner's discovery of vaccination, written by Dr. E. L. B. Godfrey, of Camden, N. J., has appeared in pamphlet form (pp. 16).

——A description of a case of recovery after extirpation of adenoid of the rectum, by Dr. Frank J. Lutz, of St. Louis, has been reprinted from the *Med. and Surg. Journal* of that city.

——Two cases of erysipelas of the lungs are reported by Dr. Wm. Porter, of St. Louis, in a reprint from the *Archives of Laryngology*. They show that this affection may occur as a primary disease.

——The *Proceedings* of the First Meeting of the Illinois Pharmaceutical Association, held in December last, at Springfield, have appeared in a pamphlet of 87 pages (Chicago: Chandler & Engelhard). It contains a full report of the discussions, list of members, Constitution and By-Laws, etc. The objects of the Association are "to elevate the pharmaceutical profession, and to protect the business."

——"Die Sterblichkeits-Ziffer *versus* Fortschritt und Modewechsel der Medicin" (The Mortality Rate *versus* Progress and Change of Fashion in Medicine), is the title of a pamphlet of 24 pages, written by Dr. Bernhard Segnitz, a New York physician. He discusses some of the various theories which have influenced the medical world in the last half century, and points out some of the undeniable steps in advance the art has made.

——Dr. William A. Hammond is now engaged in writing the biography of Servetus, who was burned, at the instigation of Calvin, in 1553, and who was, according to some, the discoverer of the circulation of the blood. Dr. Hammond will treat his subject from a theological, as well as a medical standpoint. We shall be wide of the mark if he does not furnish some "interest-

ing reading" in this biography, with various applications to the present day and its issues.

——The Biennial Report of the Board of Health for the State of Delaware, 1879, 1880, is a pamphlet of thirty-two pages, containing, besides the minutes of the meetings, essays on malaria and infant feeding. The former is accompanied by a useful table showing the relative presence of malarial diseases and others in different parts of the State. The former vary from as high as 75 per cent. to 10 per cent. of all cases. As the Report points out, this large number of malarial cases could be greatly reduced by proper sanitation.

——In a reprint from the *American Journal of Obstetrics*, Dr. E. W. Jenks, of Chicago, discusses the relation of goitre to pregnancy, and shows that in certain occult conditions of women, increased vascularity and enlargement of the thyroid gland may be produced as a consequence of some unusual excitement of the generative organs. Violent parturient efforts may cause the vascular form of goitre, but under the influence of pregnancy there may be gradual enlargement of the thyroid gland lasting for years; while, on the contrary, a goitre produced by one pregnancy is sometimes cured by a subsequent one. There are reasons for believing that, when goitre is caused by any disorder of the generative organs (excepting pregnancy), it is due more commonly to functional than to structural disease.

——Dr. Albert S. Adler, of San Francisco, discusses, in a reprint sent us, the doctrines of bilateral functions, in the light of experiments in metalloscopy. He states that the most important result of his examination is the fact that in healthy persons a simple irritation increases the sensibility of the part excited and decreases it upon the side not excited. There is no doubt that this phenomena appertains to those functions found by Adamkiewicz, and described by him under the name of "Bilateral Functions." "When in a category of these functions (secretion of perspiration) it treats of synergistic actions of the centers of organs situated symmetrically, the sensibility of the body represents a bilateral function in which the ganglia of symmetrically-situated organs are antagonistic to one another in their function."

——The *Transactions* of the Medical Society of Virginia, October, 1880, form a pamphlet of about a hundred pages. The address of the president, Dr. Henry Latham, is principally on the legal relations of the profession in Virginia. Dr. L. Ashton has an address on the relation of the profession to the outside world. Papers appear on cerebral localization, by Dr. W. C. Dabney; on functional eye trouble, by Dr. J. A. White; on the status of the medical profession in Virginia, by Dr. T. J. Riddell; and on new remedies, by Dr. C. R. Cullen. It is evident that there is urgent need for some kind of a medical law in that State. It appears that a higher qualification is demanded of a barkeeper there than of a doctor. Dr. Riddell writes:—

There are many intelligent citizens of Virginia who do not know that anybody can practice medicine in this State, without a diploma. I have frequently met intelligent persons of my city who were very much surprised when I informed them that the law of our State allowed anybody to practice medicine, irrespective of character or qualification; nevertheless, the law requires a barkeeper to establish a good character before he can obtain license to vend his beverage.

Certainly, this is most discreditable; but it is not a whit better in Pennsylvania.

BOOK NOTICES.

The Easiest Way in Housekeeping and Cooking. Adapted to Domestic Use or Study in Classes. By Helen Campbell, late Superintendent of the Raleigh (N. C.) Cooking School. Author of "Chips from a Northwestern Log," etc. 16mo. Cloth. $1.00.

The authoress of this work has produced a very useful manual for the instruction of housekeepers.

Part I of her book treats of the Situation and Arrangement of the House; Ventilation, Drainage, and Water Supply; Daily Routine of Work; Fires, Lights, and Utensils; Washing; Food and Health; Condiments and Beverages, etc. Part II treats of Marketing and Cooking, with several hundred excellent Practical Recipes and hints from the cookery of other nations; yet neither on the basis of high-spiced luxury, nor that of experiments in foreign dishes, etc., but such as are needed by the vast majority of American families, namely, people in "moderate circumstances." The peculiar value of the book lies in this fact, and in the additional one that the author leaves nothing to be done "according to taste" or "according to judgment," but specifies in each case just how much should be used. The essentials are in all cases treated first and most carefully, but the delicacies and graces and adornments of house and table find their full place, while sick-room cookery has a chapter to itself. The many recipes for breakfast and tea dishes, and relishful modes of utilizing fragments, etc., are another most valuable feature for our

wasteful American kitchens to heed. The "Household Hints," the proportioned "Weights and Measures," the "Time Tables" for cooking meats, fish, and vegetables, the "List of Utensils," "Hints to Teachers," "Tables of Lessons," "Questions for Examination," "List of Authorities," and Index of Topics, are all admirable and useful. The title of the book would seem to indicate some "royal road," but the good sense and clearness of its ideas show Mrs. Campbell's theory to be that "The Easiest Way" is the *best* way, and she certainly points it out.

Syphilis and Marriage. Lecture Delivered at the St. Louis Hospital, Paris, by Alfred Fournier, Professor, etc. Translated by P. Albert Morrow, M.D., etc. New York, D. Appleton & Co., 1881. Cloth, 8vo, pp. 251. Price $2.00.

Professor Fournier has long been known as perhaps the leading syphilologist of Paris. His lectures on the relation of syphilis to marriage were partly translated last year, in the London *Med. Press and Circular;* and one or two of them have appeared in this journal. By many, his statements are considered exaggerated, and his deductions unreliable, as drawn from exceptional rather than general results. We incline to think there is a good deal of truth in these criticisms.

In the volume before us there are sixteen chapters or lectures, eleven on syphilis before marriage, five on syphilis after marriage. The questions discussed are such as syphilis by conception, paternal and maternal heredity, conditions of admissibility to marriage, periods of immunity, the specific treatment, the use of sulphur waters, results when either the wife or the husband or both are syphilitic, the dangers to society from syphilitic persons, and the social prophylaxis which should be observed. Quite a number of notes and illustrative cases are added.

The style of the author is trenchant and the translation well done.

Drugs that Enslave. The Opium, Morphine, Chloral and Hashisch Habits. By H. H. Kane, M.D., New York City. Philadelphia, P. Blakiston, 1881. Cloth, 8vo, pp. 224. Price $1.50.

It is believed by many that there is a great increase in the opium consumption of the United States, and the statistics of imports certainly show largely augmented introductions in the last few years. At any rate, the passion for narcotics is sufficiently prevalent to make this work of Dr. Kane's quite timely.

He first examines the symptoms produced by the opium habit, and then discusses the treatment which can be adopted with the most promising results. In this part of his treatise Dr. Kane does not give the attention to institutions for the cure of this habit which he should do. The drugs and remedies he enumerates, bromides baths, electricity, etc., are of little use, apart from systematic supervision. Coca, he has tried without deriving any advantage from it—as might have been anticipated. Four chapters are given to the continued use of chloral and its effect on the system; and one chapter to hashisch, which is but little used in the United States. Chloral he does not think nearly so likely to form a habit of opium. Most of the blame for the continuance of opium and morphine consumption, he very justly lays upon the druggists, who commonly vend opium and its alkaloids without a physician's prescription. This should be prohibited by law.

John Hunter and his Pupils. By S. D. Gross, M.D., LL.D., D.C.L. Oxon, LL.D. Cantab, etc. Philadelphia. Presley Blakiston, 1881. Cloth, 8vo, pp. 106. Price $1.50.

This volume contains the first anniversary address before the Philadelphia Academy of Surgery. Hunter was an extraordinary man, and the prominent points in his career are ably set forth by the distinguished author of this sketch of his life. The facts are taken mainly from Ottley's and Home's memoirs, and are arranged with great literary skill, so as to bring out the inner life and mental character of the subject of the address. An excellent portrait of Hunter, phototyped from an engraving of Sir Joshua Reynold's portrait, accompanies the volume, and may also be had separately (price fifty cents). Among the "pupils" mentioned, of whom Dr. Gross gives short notices, were Edward Jenner, John Abernethy, Philip Syng Physick, Everard Home, James Wilson, and others. A chronological list of Hunter's writings forms an appendix to the volume.

Health Primers. The Heart and its Functions. N. Y., D. Appleton & Co. Price 40 cents.

This is a member of the English series of Health Primers. It treats of the structure and functions of the heart in popular language, describes its relations to the general system, and gives a series of maxims for maintaining the integrity of its functions. There is much of good sense in it, but it is not all good sense; thus we find, in p. 91, the extravagant statement: "Syphilis is the most common cause of by far the larger proportion of diseases which shorten life. * * It is never cured, and it may break out at any moment" (!). Certainly, such language in a popular book is out of place.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE. — COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents.

Full catalogue on application.

COOKERY AS IT SHOULD BE.

The importance of general sanitary instruction is a trite subject, but there are some directions where very much more ought to be said than has been said in relation thereto. One of these is in reference to cookery. Good food is of paramount importance to health and happiness. Nothing so dwarfs a nation as the lack of it. Perfect nutrition, as LAYCOCK so conclusively demonstrated in his writings, is the foundation of intellectual progress.

This country of ours, with its teeming fields and fertile orchards, its cattle on a thousand hills and myriads of waters rich in fishy tribes, has as yet ample nourishment for all its population and for millions in the old world. But the brute material of food is not enough. Man, wrote the author of *Sartor Resartus*, is a cooking animal; civilization is measured by the progress of this art, from the wild Tartar who readies his steak by tying it beneath his saddle, to the consummate dinner of a BRILLAT SAVARIN, where the service of the table reaches the level of a fine art, and where good digestion is sure to follow on good appetite, and health on both.

Measured by this scale, we Americans must confess to an humble seat in the Congress of civilized States. Whoever has often to partake of the horrors of the hot soda biscuits of the West, the fried pork and corn bread of the South, the pies of the Middle States, and the steaks of down East—as these useful articles are generally served at railway stations and cheap restaurants —will acknowledge that there is good reason for the ancient theory of DEPAUW, that America inclines a race to physical degeneracy.

How much of the early breakdown in American life, how much of the neurasthenia, premature exhaustion, loss of beauty and loss of mental vigor, is owing to dyspepsia, faulty nutrition, imperfect blood-making? That nervousness which Dr. BEARD says is the peculiarity of American constitutions, how much of it is to be traced directly to food, faulty, not in quantity, but in preparation? Perhaps this, much more than competition, atmospheric drynesss, violent

climatic changes, etc., is the secret of these maladies. Individually, we don't doubt it.

We have been led to these reflections by a dinner we recently ate—led to them by what psychologists call the association of contraries.

This dinner was set for twenty-five guests. There were five courses, from soup to coffee. The flavor of every dish was what belonged to the article of which it was composed, judiciously developed by proper seasoning and preparation. If it was of beans or of cabbage, it tasted of beans or of cabbage; you recognized it at once; it was just like beans or cabbage tasted when you were a boy—not like the ordinary first-class-hotel vegetable, which, with your eyes shut, you would be ready to believe was any one of a dozen species. To be sure, there were some irregularities that were at first liable to shock a conservative mind. For instance, the regulation apple dumpling is accustomed to wear a jacket of good, strong material, something like boiled felt or wash-leather; but those at this dinner were clothed in a snow-white garb, which melted into nothing when you attacked it, and your masseter muscles felt baulked of their usual combat.

There was also a very ample supply at this dinner. It answered the Spaniard's definition of a feast, which in his opinion can only be where there is *too much* to eat. Though trencher heroes and heroines were not lacking, there was enough left to have set out a supper for the party, and that in no meagre manner.

The most remarkable fact about this banquet was its cost. The total value of all the comestibles that went towards its preparation—that value, estimated at regular market rates, and not omitting even the seasoning, was $2.25—two dollars and twenty-five cents! Not that much apiece, but for the whole twenty-five guests—*nine cents a guest!* A healthful, ample, palatable, yes, epicurean repast, for nine cents!

What magician transformed such coarse and cheap food as nine cents will buy into plates that would tempt a Lucullus? What miracle extended a scanty loaf and fish to feed such a multitude?

The magicians were the ladies who superintend the New Century Cooking School, 1112 Girard street, Philadelphia, and the miracle was the secret of judicious preparation and good cooking. They are willing to make the secret an open one; it is their wish to do so, and by disseminating this knowledge all over this land, to add to the health, comfort and happiness of our people. They desire to instruct such members of their sex as take an interest in this subject in the principles of the proper preparation of food, that these pupils, thus instructed, may convey this knowledge to other cities, and in turn become instructors, and thus disseminate this knowledge in thousands of houses.

Such an undertaking comes legitimately within the province of hygiene and sanitation; and as such eminently merits the attention and support of medical men. We commend it to their consideration, whether it would not be well worth while to mention the existence and objects of this school to the families they visit, where an ignorant preparation of food costs so much in health, and also to hospitals, boarding schools and similar institutions, where a table at once economical and healthful is such a desideratum. Full information can be had by writing to the address above given.

We have not space to refer to other advantages accruing from an improved *cuisine;* how it tends to lessen the craving for stimulants; to diminish the mortality of children; to increase the joys of domestic life; to assuage the sufferings of the invalid; to relieve the pressure of a narrow income; to allow more to be expended in culture and charity; and in many other ways to make life more worthy and worth living. All these suggestions will readily present themselves to the reflecting mind, and lead us to hope that the next philosophical gastronomist will have another kind of chapter to write on cookery in America than that in Brillat Savarin's famous book, which we close by quoting in full.

La Cuisine en Amerique.

Notes and Comments.

Hypnotism, Catalepsy and the Faculty of Speech

It will not be at all amiss, in connection with the recently reported experiments in hypnotism of Prof. Hammond, to mention a memoir by M. Ballet, which appeared in a recent number of *le Progrès Medical.*

This memoir gives a curious means of demonstration, in the living subject, of the cerebral localization of the faculty of speech in the left hemisphere.

It is well known that for several years M. Charcot has plunged his hysterical patients at the Salpetrière into the hypnotic or cataleptic, state as he chose, and by means as simple as those of Prof. Hammond.

These two conditions differ essentially; hypnotism is characterized by the following peculiarities: 1. When the limbs are elevated they do not remain in position, but fall when the support is withdrawn; the muscles and nerves are, however, in an excitable state, and irritation of any particular nerve induces contraction in the corresponding muscles with as much precision as the localized electrization of Duchenne of Boulogne. 2. The faculty of speech remains, the patient replies to questions, counts or recites verses, as he is commanded; he is even able to write or communicate with those about him by gestures. While in this hypnotized condition the patient may be, with facility, thrown into the cataleptic state. To bring this about it suffices to lift the eyelids and allow the light to influence the retina. The scene then changes completely; the hyper-excitability of nerves and muscles disappears; the limbs remain in whatever position they are placed; it is true catalepsy.

2d. What is yet more remarkable, every external intellectual manifestation is abolished; the patient no longer speaks or answers questions.

But what is even more astonishing, a patient may be placed in these two conditions at one and the same time; the right half being in a cataleptic state, while the left is in a hypnotic slumber, and *vice versa.* In order to bring this about the patient is hypnotized as usual, then one eyelid is raised while the other eye remains covered. Under these conditions the cerebral hemisphere which corresponds to the covered eye (on account of the crossing (entrecroisement) of the filaments of the optic nerve this is the opposite hemisphere) remains in a hypnotized state, while the hemisphere corresponding to the uncovered eye enters on a cataleptic condition.

Thus in this subject there exists at the same time a state of hemi-lethargy and hemi-catalepsy. M. Lepine originated, in Charcot's service, the experiment which we will briefly present, and which is at present daily repeated at the Salpetrière. A hysterical patient is hypnotized; she speaks, reads, and writes while in this state; the left eyelid is raised, and the right hemisphere thus plunged into a cataleptic condition, and the patient continues to speak and gesticulate. But if, on the other hand, the right eye be uncovered, that is, if we place in the cataleptic state the left hemisphere, the presumed seat of the faculty of speech, the scene changes. The patient suddenly becomes silent, she no longer answers questions; the phrase commenced remains unfinished; the patient no longer makes sign or gesture.

A hysterical patient in the hypnotic state is commanded to count, and does so automatically. We suddenly uncover the left eye (right hemisphere), there is no interruption in the enumeration; we lift the right eyelid (left hemisphere); there is sudden arrest in the counting, but the patient recommences as soon as the eyelid is dropped.

Significance of Tendon Reflex.

This is discussed in a recent paper by Dr. H. Senator, of Berlin, editor of the *Centralblatt für Med. Wiss.* It is well known that a sharp blow on the tendon of the patella, when the legs are crossed, will cause the leg to be raised by the sudden contraction of the quadriceps extensor femoris, and a movement of the foot can be induced by a similar blow applied to the tendo-Achillis. Tschirjew has shown that in the rabbit the centre for the reflex act in the patellar-reflex is situated between the fifth and sixth lumbar vertebræ, the afferent fibres proceeding from the tendon, and not, as Joffroy maintained, from the skin. These fibres run in the crural nerve, the division of which puts an end to the phenomenon. Senator corroborates Tschirjew's statement that division of the spinal cord opposite the fifth or sixth lumbar vertebra abolishes patellar tendon-reflex. He finds, further, that division of one lateral half of the spinal cord at this level abolishes the reflex on the corresponding side only. There is, therefore, no decussation of the nerve fibres. Division of the lateral column on one side produces the same effect. Division of the posterior cornua of the gray substance does not abolish the tendon-reflex. He concludes that in this part of the lumbar region both the sensory and motor fibres of the posterior extremities are exclusively contained in the

lateral columns of the cord. It is remarkable that the patellar tendon-reflex can only be induced by one kind of stimulation—namely, mechanical shock or sudden extension by a blow. Neither electric, chemical, nor thermic stimuli have any effect. Nor has such stimulation as can be applied by pricking, cutting, or pressure. Senator discusses the views of Tschirjew in regard to its presence in health and disease, and appears to think that it is not always demonstrable in health, and not always absent in ataxy.

Value of Venesection.

A correspondent writes to a recent number of the *British Medical Journal:* "I heartily agree with Sir James Paget, who says that 'we undoubtedly overvalue the blood, and estimate too cautiously the loss of it,' etc. I can testify from personal experience that venesection is the remedy *par excellence* for scarlatinal uræmic convulsions. During the summer of last year, I unfortunately caught scarlet fever, which was followed by uræmic convulsions. The convulsions came on one night, and were preceded by a few hours by intense frontal headache, vomiting, defective vision, muscular twitchings in the legs, shoulders, etc. After I had had two or three convulsive fits, I was bled to two pints. Mustard poultices were also applied to the legs, and ice to the head, etc. Soon after the venesection, I think, I had two more fits, but they were not so strong as the former ones. My sight returned so that I could distinguish people after two days."

Food for Infants.

A prize was offered by the Paris Academy of Medicine last year, for an essay on the artificial feeding of infants. The essays show that there is some lack of unanimity in opinion.

The vexed question as to how far the milk should be diluted still remains unsettled, and gastro-intestinal disturbances are variously ascribed to the dilution of the milk or the want of it. In connection with this question, it has been well suggested that milk given fresh from the udder of an animal is to a great extent a living aliment, and much more easy of digestion. Possibly, also, the difference between country and town-fed animals may influence the necessity for the addition of water, and it may be possible to increase the tenuity of the milk by inducing a more frequent drinking on the part of the animals which supply it. No hard and fast rule, however, can be laid down on this subject, but the tolerance of the digestive organs may always be taken as the guide. The addition of a small quantity of sugar is generally recommended, though the possibility of its inducing intestinal derangement is not to be overlooked. A few grains of common salt was proposed by two of the writers. Artificial substitutes for milk were all but universally condemned. The importance of most careful supervision of artificial feeding was emphatically insisted upon, and the contrast between its pursuance at home and in public nurseries was shown by the following figures. The mortality of children fed by mothers was 10 to 16 per cent.; by wet nurses, 26 to 30 per cent.; by artificial feeding at home, 15 to 20 per cent.; and away from home, 50 to 60 per cent. The great dangers of the last mentioned system are forcibly dwelt upon.

London Fogs and Health.

The eminent sanitarian, Dr. Alfred Carpenter, has a paper on "London fogs," in the December number of the *Journal of the Society of Arts.* He discussed with much ability the causes of the intensity of town fogs, the means for their prevention, and how to set these means in operation. The question is a serious one, as appears by a paper by Dr. Arthur Mitchell, published in the *Journal of the Scottish Meteorological Society*, vol. v. Dr. Mitchell speaks of the fogs that prevailed in London from November, 1879. to the end of the first week in February, as forming one continuous fog, "constituting one of the most remarkable on record in this country." He shows that: (1.) The whole death rate was enormously increased. (2.) No approach to so large an increase of the death-rate showed itself in any other of the British large towns. (3.) Asthma is the disease which appeared to be most directly increased in its fatality by the fog, In the first three weeks of 1880, when the fog more or less completely disappeared, the death from this disease fell at once to about 30 per cent. below the average, having previously risen in the middle of December, when the fog was severe, to 43 per cent. above the average, and rising again in the end of January and beginning of February, when the fog was densest and most persistent, to 220 per cent. above the average. The death-rate in London rose in the first week in February, when the fog was worst, to the enormous ratio of 48 per thousand. Considering all this, it is not to be wondered at that men of science have been at work to devise means to rid London of its fog, if possible.

The Composition of Podophyllin.

The London *Med. Times and Gazette* states that the composition of the product of the podophyllum peltatum, which is known as podophyllin, has just been subjected to careful investigation by Dr. Podwyssotzki, assistant in the Pharmacological Institute at Dorpat (*Archiv für exp. Path. u. Pharm.*, xiii, page 19). The principal constituents were found to be three. The first is a colorless substance which crystallizes with difficulty, is soluble slightly in water, but freely in alcohol, with an excessively bitter taste, and has a very slightly acid reaction in alcoholic solution. This substance, for which the name of podophyllotoxin is proposed, is a powerful poison—one to five milligrams killing a cat. The second constituent is a body which the investigator calls picropodophyllin—crystalline, neutral, insoluble in water, intensely bitter, and physiologically active. Podophyllic acid, an intensely acid substance, soluble in warm water, and combining with alkalies, completes the important constituents of podophyllin. The same constituents can be obtained from the rhizome. With respect to the physiological action of these bodies, the podophyllotoxin possesses all the well-known properties of the resin. Picropodophyllin possesses the same, but in a greatly inferior degree. Podophyllic acid is physiologically inert. Podwyssotzki is strongly inclined to believe that the picropodophyllin and podophyllic acid, which can be obtained from podophyllotoxin, are due the decomposition of that body by an alkali.

On the Abortive and Curative Treatment of Smallpox.

"On the 16th January, 1880," says Dr. Bouyer, of St. Pierre de Fursac, in the *Bull. de Thérapeutique*, December 25th, "I addressed to the Academy of Medicine the following letter:—'I have the honor to forward to the Academy a sealed packet containing a formula for what I believe to be the curative and abortive treatment of smallpox, and which I have found very successful in six cases. When I have tried the treatment in a greater number of cases, I shall lay before the Academy the results of my investigation.'"

On the 16th March, Dr. Bouyer had had fifteen cases, all confirming the efficacy of the remedy, and shortly afterwards he was pleased to make it known. The following is the formula recommended:—

℞.	Alcohol,	10–15 grams (2½–4 ʒ)	
	Salicylic acid,	1 gram (15 grs.)	
	Simple syrup,	20 grams (5 ʒ)	
	Water,	50 grams (2 ℥).	M.

Of this a tablespoonful should be taken every six hours if the case is seen early, and every four hours if the disease is well advanced before the treatment is begun. Dr. Bouyer finds that under this treatment, commenced early, the eruption is discrete, or if confluent, the pustules are of small size, and contain little pus. They contract between the sixth and eighth day, leaving light furfuraceous crusts, which fall off in a few days without leaving either cicatrices or stigmata. The fever of suppuration is always greatly diminished.

Desiccated Ox-Blood and Hæmoglobine.

Dr. Le Bon, in the *Journal de Thérapeutique* (November 25) protests against the claim which Dr. Andrew Smith and others in America have made, of having invented this preparation, the full description of which he had published five years since in the *Comptes-Rendus* (1875), and notices of which were given in all the French medical journals. It has now, he states, been well tried at the Paris hospitals, and especially by Prof. Bouchut at the Children's Hospital, and has been found most efficacious in all cases in which reconstitutents are required, and succeeding where the martial preparations fail. It is indicated wherever iron, raw meat or the phosphates are useful. Hæmoglobine, Dr. Le Bon says, is difficult to prepare, and in some modes of desiccation of blood all hæmoglobine is lost. He has had it prepared by a skillful chemist, and it is now in the trade. It is almost completely soluble in water, giving to this a magnificent red color. It may be given in this way or with chocolate, or in the form of powder. The American plan of adding alcohol he criticises, as this precipitates the albumen. Dr. Le Bon observes that all the elixirs or wines sold as containing any of the essential principles of blood or meat are an entire delusion, as they cannot contain an atom of the albuminoid principles which give to meat its nutritive properties.

Foreign Bodies in the Uterus.

Le Praticien publishes two interesting cases: in the first, the physician, finding himself in the presence of dangerous hemorrhage from the uterus, introduced into and left in the organ a sponge wet with aromatic vinegar. When the hemorrhage ceased it was not considered expedient to remove the sponge, and the os uteri soon closed so that the extremity of the index could not be introduced. The next day, when about to dilate the os, the physician was agreeably surprised at finding the sponge in the vagina.

In the second case an accoucheur, obliged to introduce the hand to separate an adherent placenta, found that he had slipped off and left in the organ a rather loose finger ring. Nothing was done until two days later, when, as there was slight hemorrhage, he made a vaginal examination, found the os somewhat dilated and the ring just behind it; he was able to withdraw it with the bent finger. M. Hugues concludes, from these facts: 1. That foreign bodies introduced post-partum into the uterus are not liable to induce serious accidents, and, 2. That the uterus itself often induces the expulsion of foreign bodies introduced into the organ.

Correspondence.

A Health Resort in Northern Georgia.

Ed. Med. and Surg. Reporter:—

About two years ago my attention was first called to the superiority of the climate of certain parts of Georgia, with reference to the treatment of consumption, by Dr. J. M. Keating, of Philadelphia, whom I met at Delhi, India, in company with General Grant and party, on their tour around the world. Dr. Keating, who has devoted much of his time to climatological researches, and had spent a portion of a winter in Georgia, with an invalid, was quite enthusiastic on the subject, and declared that, as regards health and comfort, he would rather live in Georgia than in any other part of the United States.

Bath, a little village in Richmond County, about sixteen miles from Augusta, in a southwesterly direction, and seven miles southeast of Berzelia, on the Georgia Railroad, is universally regarded as the healthiest spot in this State, and has, since 1812, been a favorite summer resort with the planters from the surrounding malarial districts, and many of the wealthy citizens of Savannah, Augusta, and other neighboring cities, who annually flock hither with their families, in order to escape from the scorching heat of the valleys with its attendant evils, malaria, mosquitoes, etc. etc. Of late, a few invalids from the North have spent the winter months here, and have, I believe, without exception, returned to their homes in the spring much benefited. As this place possesses in a more perfect degree than any other locality in the United States with which I am acquainted, those climatic conditions that are now considered by high authorities to be necessary for the successful treatment of phthisis, viz., altitude, dryness of atmosphere, and a mild and equable temperature, which enables the invalid to live, as it were, out doors; yet is sufficiently cool and bracing to render active exercise in the sunshine agreeable, I think it deserves a wider reputation than it has hitherto enjoyed. Mr. Wingate, a gentleman from Maine, who for many years has traveled with his son, and spent several winters in the Bahamas, Florida, Mexico, California, and the two last here, says that he considers this climate superior to that of any of the above named regions. Dr. J. M. Dent, who has been practicing his profession here for thirteen years, states that during that time he has not met with a single case of malarial fever, typhoid fever, pneumonia, or consumption, which originated in Bath; although while practicing in one of the neighboring counties he averaged during the winter months fifteen cases of pneumonia a day; he moved to this place himself for his health, and declares he would rather live here on corn bread, than elsewhere on all the luxuries that wealth could procure.

Although no meteorological record has hitherto been kept, the winter temperature ranges, as far as I can learn, from 40° to 60° Fahr., with an occasional frost and a slight snow-fall once in half a dozen years; the past winter has, however, here as elsewhere, been exceptionally severe. The soil being sandy, the roads are perfectly dry half an hour after even a heavy rain shower, but rains are by no means frequent, and when they do occur it is usually at night, the sun rising again in the morning on a clear and bright sky sending forth his life-giving light unimpeded by a single cloud. The village of Bath is built on several hills, at an elevation of about 900 feet above the sea, and being surrounded by dense pine forests the atmosphere is constantly charged with those terebinthinous vapors, the inhalation of which we know is at present regarded as one of the most efficacious remedies in the treatment of pulmonary, laryngeal and nasopharyngeal diseases. A clear stream of water runs through the village, and an elegant bath house with swimming arrangements has been erected for the use of the inhabitants and visitors. Numerous excellent springs, some of which contain iron and magnesia, burst forth from the earth in various places. There is no hotel in the place, which I regard as an advantage, hotels offering anything but comfort to invalids, who, moreover should never be crowded together in one house, but rather scattered about among healthy people; large, comfortable and airy rooms, with first class board, may, however, be had at reasonable rates ($15 to $25 a month), in private families, and there being a plentiful supply of good wood, huge fires will always be found blazing on the hearth during the cold season, adding materially to the cheerfulness of the surroundings as well as to the maintenance of perfect ventilation. Another advantage which I think this place possesses is that it is some distance off from the railroad, invalids thus escaping the noise and bustle of the arrival and departure of the trains, and the town being kept free from that rowdy element which always accompanies the iron horse. As for outdoor amusements, there are excellent hunting grounds, and the numerous good roads which extend in all directions offer facilities for riding, either in carriage or on horseback, the latter healthy exercise being at present much in vogue and practiced daily by the younger and more active of the visitors, while nothing can be more pleasant than a promenade in the woods on a bright, sunny day, or a game of croquet on the large open lawn in the village. There are at present two physicians at Bath, Dr. Dent, who, as above stated, has been practicing his

profession in this place for thirteen years, and myself, who, though but a short time here, have been so favorably impressed with the place and its surroundings that I intend to move my family here at once. A collegiate institute is about to be established, with the Rev. Paul C. Morton as Principal, assisted by experienced teachers, in which instruction may be had in all the English branches, ancient and modern languages, physiology, chemistry, etc., and this I regard as of special advantage to delicate youths and young ladies who, through ill health, are unable to pursue their studies in the North.

Bath, Ga. JOHN C. SUNDBERG, M.D.

Special Branches of Medicine.

ED. MED. AND SURG. REPORTER:—

In looking over the REPORTER of last week I came across a communication by Chas S. Turnbull, M.D., of Philadelphia, on "Nasal and Pharyngeal inflammations, considered with reference to diseases of the middle ear; with remarks upon treatment;" which I read with a great deal of satisfaction and interest.

The subject is treated entertainingly and practically, and it is the complete conviction of the truth of my experience that leads me to comment on a subject of so vital importance. Every medical practitioner is constantly meeting with cases of disease peculiar to these organs, some of which may be classed among the most formidable affections. In the large cities not a few devote their exclusive attention to the practice of their chosen specialty; still they are unable to treat every case that occurs, and consequently the general practitioner is almost daily encountering cases which demand special treatment. Hence it is important that the general practitioner should be acquainted with the literature and best means of diagnosis and treatment of these diseases. That many promising cases from which good results might be obtained are never treated cannot be gainsayed. They are perhaps diagnosticated; but inasmuch as many physicians never meddle with these organs, or the patients are perhaps treated without benefit, they abandon all treatment and become nearly reconciled to the inevitable, when their hopes are again revived by reading flaming newspaper and almanac advertisements, and the patient invests in some patent medicine or secret treatment, or perchance consults some traveling medicine vender, some charlatan or quack, who makes unwarrantable pretensions to skill, promising cure for all diseases that human flesh is heir to, is fleeced of his money, and eventually goes down to his fate.

I have no question in my own mind, but that our ideas and treatment of idiopathic inflammations of the mucous membranes of the nose, pharynx and middle ear must be radically changed, and that the common and vague term "catarrh," which is applied to almost every variety of head troubles, will soon have a place only in the evening mist and mysteries of the past, not able to stand the noonday sun. The detection and efficient treatment of this class of cases are so tersely expressed by Dr. Turnbull in his valuable communication, that it seems wonderful that it should ever be neglected. And, in reviewing the subject of aural and ophthalmic surgery, as well as rhinoscopy and laryngoscopy, as rationally practiced, when contrasted with the stereotyped course as followed by most physicians, many deductions may be drawn. We not only find much to learn but much to unlearn. I am a country practitioner, and have not attained, nor do I expect the amount of operative success of those who practice their chosen specialty exclusively. Yet I have the gratification to see some evidence, at least, that my labors in these various special branches of medicine have not been in vain. And the surest way of gaining that end is by studying and paying due respect to the rules, methods and precepts of the acknowledged "lights," in these special branches of medicine and surgery.

Therapeutically we have been struggling in the dark, both in general and special medicine; but science seems to be on the verge of letting in the dawn of a new day, and the readers of our valuable MEDICAL AND SURGICAL REPORTER are catching the rays transmitted and thrown off by these "special lights," thereby receiving constantly useful information, and through this reading become better qualified to perform the duties of the profession. Medical journals nurture and form a taste for reading when the text-books have lost their interest. They have led many of the profession to cultivate a talent for writing, and in this way science has been advanced. New remedies, pathological views and methods of treatment are thus made known to the readers of journals long before they are embodied and collected in standard works. Therefore let the men engaged in special branches make their experience, their methods and plans of treatment known through the journals, for the benefit of their professional brethren, who, feeling the greatness of their mission, labor for the welfare of mankind. I am well aware that the specialist is often accused of being "*Novitatis potius quam veri studiosus*," but it must be borne in mind that the medical art is progressive. It has much to learn, and there yet remains very much land to be possessed in the work of original investigation; and this applies to all branches of medicine. Hence let the general practitioners of medicine, men who have had the opportunity of noting the progress of medicine, who have observing minds and mature judgments, such men as Dr. Traill Green, Dr. Hiram Corson, and a host of others who might be mentioned, who show, as their years increase, their activity and professional enthusiasm does not diminish, let these men keep their pens in motion; they take active interest in medical progress, and what they write has weight; their writings are always acceptable and impart sound truths. The physician who reads medical journals with regularity is always furnished with some new hints, and keeps abreast of medical progress. We are always learners, and find that much needs to be supplemented, both in knowledge and experience, to become masters of the science and expert manipulators of the art. "Work, watch and wait," should be every physician's motto, and he should be satisfied with no attainments, however high. The *ultima thule* lies beyond.

Bath, February 22d, 1881. G. T. FOX, M.D.

Scarlatina and Smallpox.

Ed. Med. and Surg. Reporter:—

For the purpose of awakening thought suggestive of a rational treatment of these much dreaded and oft fatal diseases, which prevail so alarmingly, I offer these views. My knowledge is obtained more from books than from experience, and is presented as a rational theory of treatment proper for these acute exanthems.

The action of the atmosphere upon wounds is well understood, in the processes of secretion, suppuration and desiccation of the secretions, by which granulation and healing is made possible. Without the exclusion of the air from the raw surfaces of wounds by natural or artificial means there could be no cicatrization; hence the propriety of protecting the inflamed and sensitive surfaces from the action of the atmosphere in exanthematous diseases. If the secretions were repeatedly wiped out of a wound, and it was left exposed to the atmosphere, it would never heal. Bearing these facts in mind, in reading many hospital and physicians' reports of their mode of treatment in scarlatina, I found in many instances, and especially in those successfully treated, incidental allusion to bathing and inunction, and these confirmed my convictions that exclusion of the surface of all efflorescent patients from the action of the atmosphere should be a part of a rational treatment. On one occasion I was called to see a patient suffering intense pain, whose entire surface presented the appearance of a boiled lobster; the effloresence was exceedingly aggravated and skin sensitive; the patient was, to my mind, being pained to death! At once I prepared an antiseptic bath, of normal flesh heat (which was cooling and grateful to the patient suffering from a fever heat), and while being sponged the patient dropped into a sweet, refreshing sleep. After the temperature was somewhat reduced by the tepid bath, the patient was anointed with a bland, antiseptic ointment over the entire surface. By daily use of the sponge bath, which was immediately followed by inunction, the patient soon convalesced, with but little trouble from the usual *sequelæ*. Had the bath and inunction been used on the first appearance of the eruption, in my opinion, there would have been no symptoms of the *sequelæ*.

In some cases of *variola*, to prevent pitting, physicians protect the face from the atmosphere by using oiled silk coverings. And in your journal of the 19th inst. (page 217), Dr. Schwimmer advises a mask of pliable linen for the face, to be smeared with liniments composed of carbolic acid, olive oil and chalk, or starch, to prevent pitting by smallpox.

Now, if the pitting of the face can be prevented by protecting it from the action of the air by oiled silk, or by carbolated ointments, thereby preventing the enlargement of the pustules, and increased ulceration, why not protect the entire person from the poisonous action of the air, and thereby lessen the ulceration and the production of pus and virus, and save the patient, not only from *pitting*, but from *dying* from the secondary fever caused by the absorption of this accumulated virus, resulting from the action of the atmosphere. Wounds properly protected from the atmosphere generally heal by *first intention*, and without the generation of pus. Whence, then, the great amount of pus in extensive suppurating wounds? Not from within, but from the poison without. Whence the immense quantity of virus-pus that covers the patient suffering from confluent variola? It cannot come from within altogether.

Without speaking of the various prescriptions used by physicians in the treatment of these diseases, many of which are proper, I have briefly hinted at what I believe to be the *rationale* and the *desideratum*, in the treatment of the diseases named, believing that by the use of antiseptic baths, and antiseptic ointments, which exclude the air, and also the light (if pulverized charcoal was used in the ointment), *nine tenths of the deaths that occur in the secondary fever in variola may be obviated!*

John Brooks, M.D.

Sinnamahoning, Pa., Feb. 23, 1881.

News and Miscellany.

American Medical Association.

The following announcement has been sent us for publication:—

The Thirty-second Annual Session will be held in Richmond, Va., on Tuesday, Wednesday, Thursday and Friday, May, 3, 4, 5, 6, 1881, commencing on Tuesday, at 11 A. M.

"The delegates shall receive their appointment from permanently organized State Medical Societies, and such County and District Medical Societies as are recognized by representation in their respective State Societies, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States."

"Each State, County and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number: Provided, however, that the number of delegates for any particular State, territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association."

Secretaries of Medical Societies as above designated are earnestly requested to forward, at once, lists of their delegates.

SECTIONS.

Practice of Medicine, Materia Medica, and Physiology: Dr. Wm. Pepper, 1811 Spruce street, Philadelphia, Pa., Chairman; Dr. T. A. Ashby, Baltimore, Md., Secretary.

Obsterics and Diseases of Women and Children: Dr. James R. Chadwick, cor. Marlborough and Clarendon streets, Boston, Mass., Chairman; Dr. Joseph Taber Johnson, Washington, D. C., Secretary.

Surgery and Anatomy: Dr. Hunter McGuire, Richmond Va., Chairman; Dr. Duncan Eve, Nashville, Tenn., Secretary.

State Medicine: Dr. James T. Reeve, Apple-

ton, Wis., Chairman; Dr. R. G. Jennings, Little Rock, Ark., Secretary.

Ophthalmology, Otology and Laryngology: Dr. Dudley S. Reynolds, Louisville, Ky., Chairman; Dr. Swan M. Burnett, Washington, D. C., Secretary.

Diseases of Children: Dr. A. Jacobi, 110 W. 34th street, New York, Chairman; Dr. T. M. Rotch, 77 Marlborough street, Boston, Mass., Secretary.

A member desiring to read a paper before any Section should forward the paper, or its title and length (not to exceed twenty minutes in reading), to the chairman of the Committee of Arrangements, at least one month before the meeting.

Committee of Arrangements. Dr. F. D. Cunningham, Richmond Va., Chairman.

Amendment to the By Laws, offered by Dr. J. M. Keller, Ark.: In the election of officers and the appointment of committees by this Association and its President, they shall be confined to members and delegates present at the meeting, except in the Committees of Arrangement, Climatology and Credentials. W. B. Atkinson,
Permanent Secretary.

The International Medical Congress.

We have received from Dr. C. T. Hunter, Local Secretary, the programme of the Seventh Session of the International Medical Congress. As before announced in the Reporter, the President is Sir James Paget, Bart. The Chairman of the Executive Committee is Dr. Risdon Bennett; of the Reception Committee, Prescott Hewett, Esq., F.R.S. The published rules are as follows:—

Rule I. The Seventh Session of the International Medical Congress will be opened in London, on Tuesday, the 2d of August, 1881, at the Royal College of Physicians, Pall Mall, where the Executive and Reception Committees will meet the members, between the hours of 4 P.M. and 7 P.M. The meetings for business will commence on Wednesday, August 3d, and will end on Tuesday, the 9th of August.

Members will be registered and tickets issued on the 2d of August, and on succeeding days, during the session of the Congress, at the office of the Reception Committee, at the College of Physicians, Pall Mall, between the hours of 9 A.M. and 5 P.M.

Tickets may also be obtained beforehand from the Reception Committee, by intending members, on payment of their subscription and upon their making a properly authenticated application.

Rule II. The Congress will be composed of medical men, legally qualified to practice in their respective countries, who shall have inscribed their names on the Register of the Congress, and shall have taken out their tickets of admission. The subscription is fixed at one guinea, which amount is to be paid on inscription and before the commencement of attendance at the meetings. Each member of the Congress will be entitled to a copy of the Transactions when published.

Rule III. Ladies invited by the Reception Committee may be present at the Social Meetings of the Congress, but may not attend the Business Meetings.

Rule IV. The work of the Congress is divided into fifteen sections; and Museums of objects of scientific and professional interest will be on view during the meeting.

Rule V. A President of the Congress, Vice-Presidents of the Congress, a Secretary-General, as well as a President, Vice-Presidents, Council, and Secretaries for each Section have been nominated, but the definitive election of officers will be made by the Congress at its meeting on August 3d, when a certain number of Honorary Presidents of the Congress will be elected. Honorary Presidents of the Sections will also be elected by the Sections.

Rule VI. The first general meeting of the Congress will take place on Wednesday, August 3d, at 10 A.M., in St. James's Hall, Regent street, when the Congress will be constituted, and the President will deliver an Inaugural Address; and at three o'clock on the same day the Sections will meet for the transaction of business in the rooms allotted to them. The Congress will subsequently assemble twice daily, from 10 A.M. to 1 P.M., for Sectional meetings, and from 4 to 5.30 P.M. for general meetings. Any Section requiring additional time may meet from 2 to 2.30.

Rule VII. The general meetings are reserved for:—

1. The transactions of the general business of the Congress.

2. Addresses or communications of scientific interest more general than those given in the Sections.

Rule VIII. Questions which have been agreed upon for discussion in the Sections will be introduced by members previously nominated by the officers of the Section. The members

Rule XII. The rules, programmes, and abstracts of papers will be published in English, French, and German.

Each paper or address will appear in the transactions in the language in which it was delivered by the author. The debates will be printed in English.

To ensure accuracy and facilitate the publication of the proceedings, speakers are requested, before the conclusion of each meeting, to hand to the Secretaries of the Section, in writing, the substance of their speeches.

Rule XIII. The President of each Section will direct the discussions in it, according to the rules usually observed in deliberative assemblies.

He will decide upon the daily programme in conjunction with the officers and council of the Section.

Rule XIV. The Executive Committee reserves the power to permit the attendance at business meetings of medical students and of other persons interested in the work of the Congress, on the recommendation of the Executive Committee, or the officers of a Section, and the payment of half a guinea. These persons will not be allowed to take part in the proceedings.

Rule XV. Questions relating to the business of any of the Sections must be addressed to the Secretaries of that Section.

All other communications should be sent to WILLAM MAC CORMAC, Esq., Hon. Secretary General, 13 Harley street, London, W.

Smallpox in Philadelphia.

This has been a prosperous winter for varioloid in Philadelphia. Two or three deaths a week from it were reported for the first eight months in the year. Beginning with the first of September last, there was a marked increase in the number of deaths from the disease, which increase has steadily continued to the present time. During the first week in September there were eight deaths from smallpox in Philadelphia; during the first week of the present month, February, there were 61 deaths from the same disease. During the whole period, twenty-four weeks, from the 1st of September to the 12th of February, there were six hundred and fifty-six deaths from smallpox. The total deaths in Philadelphia, during this period, was 7967; the deaths from smallpox were, therefore, 8.2 per cent., or one in twelve of all the deaths.

Commenting on these facts, Dr. E. S. Snow, of Providence, forcibly remarks:—

No principle of sanitary science is more positively established than this, that there is an absolutely certain individual preventive of smallpox, which is easily obtainable and easily applied. The whole question of the arrest of this disease, at any time and in any place, is simply the question of the faithful application of this preventive, with other suitable well-known sanitary measures.

If this preventive and these sanitary measures had been faithfully applied on the appearance of the first case of smallpox in Philadelphia, the whole subsequent disease, suffering, loss of life and loss of money would have been prevented at an expense of a few dollars. If the same measures had been faithfully carried out in the first ten cases of the disease, the same result would have been obtained at an expense of a few hundred dollars.

With each week's delay, and increase of new cases, the trouble and expense of arresting the disease have been greatly increased; but at no time, from the beginning to the present moment, has the complete arrest of the disease by suitable measures been impossible, or even doubtful.

Peculiarities of Race.

The report of Dr. Smith, stationed with the troops at Fort Clark, Texas, shows that there is quite a difference in taste between the white and negro troops at that place. The troops are furnished with certain rations. If they do not care for these they can sell them and purchase other groceries and supplies in their stead. The doctor finds that the negroes sold most of their coffee and salt, whence it might be inferred that they did not appreciate these articles. On the other hand, the white troops sold their pork and bacon and pepper. A curious circumstance was the fact that the negro soldier consumes twice as much sugar as a white one; a still stranger fact, the declaration that the darkies use, on the average, three times as much soap as their white brethren.

Peacemakers.

When Dr. Gatling, the mildest-mannered, most benignant of men, conceived the notion of that murderous instrument known as his gun, he perfected its slaughtering prowess in the "interests of peace." Make such an instrument as will render battle simply slaughter, and we shall have no wars, was his axiom. Another bloodthirsty advocate of peace is experimenting, at Washington, with an instrument of possibilities so bloody and death-dealing that Dr. Gatling's monster may be considered a boyish toy in comparison. This peacemaker is also a doctor—Dr. McLane—and his gun ranges from the size of a handy horse pistol to a one hundred and fifty pounder, and its power of destruction may be likened to the simoon on the desert careering over a helpless caravan.

Pharmaceuticals.

MEDICINAL WHISKY.

A pure article of stimulants is a most important aid in therapeutics, and so much of the ordinary spirits on sale in drug stores is inferior deleterious stuff, that we mention with pleasure the effort of the Newbold-Buchanan Distillery Co., Louisville, Ky., to put at the command of all an entirely sound whisky. It is put up in bottles, so corked and labeled that any tampering with the cork and any refilling of bottles with a lower grade is impossible. The cases are retailed at $12.00 each, and some excellent judges to whom we presented a sample sent us, pronounce it old, pure, soft, and of full flavor. We have every confidence that it merits in an unusual degree the endorsement of the profession.

"Winter Cholera" and "Butterine."

A Chicago despatch of Feb. 28th states that a number of prominent physicians, interviewed for the *Tribune*, give it as their opinion that the disease known as "winter cholera," which has prevailed to an alarming extent in that city during the winter, is traceable to the extensive use of "butterine," in the composition of which hog products largely enter, and not to the Lake water. They say the process of making the compound does not require the high temperature which is necessary in refining lard; and that the germ of the disease might pass through the process without being killed.

Items.

—The National Board of Health *Bulletin* states that the relative mortality of the white and colored cannot be given with any accuracy until the late census shall furnish the respective populations for a sufficient number of cities. The reports of 1879 and 1880 indicate, however, that the mean annual death-rate of the whole white population is not above 20 per 1000, while that of the colored people is above 30. The ratio of two to three will nearly express the relative mortality, so far as it has been determined by reports based on an imperfect estimate of population.

—By a decision of the Supreme Court of this State the bequests of the late Prof. Geo. B. Wood to the Medical Department of the University of Pennsylvania, for the maintenance of the auxiliary Faculty, will have to be reduced, in proportion to the general depreciation of the estate. This may jeopardize the continuance of the auxiliary Faculty.

—M. Oscar Comettant has just started, in Paris, a periodical, entitled *Nouveau-né*, of which the object is to give counsel as to the proper treatment of infants during the first year of their life. A copy of the first number, accompanied by a letter from M. Comettant, was sent to Victor Hugo, who acknowledged its receipt in a note, in which he said: "Your letter moves me. I applaud you. Everything you may do for infancy you will do for humanity. Forget not that this sweet infancy, trembling and naked, brings to us, in its arms, the future."

—All the physicians at Hoosick Falls, New York, have agreed to respond to no calls from families who have unpaid bills more than three months old.

OBITUARY NOTICES.

—At the regular annual meeting of the Faculty of Starling Medical College, held February 26th, 1881, the death of Prof. Francis Carter, Dean of the Faculty, was announced. The regular business was suspended, and the following resolutions, expressive of the sentiments of the Faculty, were adopted:—

"*Resolved*, That in the death of Prof. Francis Carter, our beloved Dean, we have lost an accomplished and genial colleague, a wise counsellor and faithful guide, and that we tender to his family our heartfelt sympathy; and

"*Resolved*, That we attend the funeral in a body, and that the halls of the College, which was founded mainly through his influence, and over which he has for many years presided with dignity and efficiency, be draped in mourning for thirty days."

—Dr. Arthur Clifford, a son of ex-Governor Clifford, of Massachusetts, while returning from a short trip to New York, with Dr. Ira Russell, shot himself through the heart in a Ware River train, between Barre Plains and Winchendon. He had been partially insane.

—Dr. George W. Dirmeyor, a well-known physician, for many years Secretary of the Louisiana Board of Health, died in New Orleans last week, aged 52 years. A few days before Dr. Dirmeyor had stated that he had seventy-seven hemorrhages of the lungs in the past twenty-seven years.

—Dr. John S. Winans, a well-known physician in Allegheny, died at his residence in that city on the 5th ult., in the 68th year of his age. He was born in Milton, O.; graduated at the Ohio Medical College, Cincinnati, in 1845; practiced his profession for many years at New Brighton and Rochester, Pa., and removed to Allegheny in 1870.

QUERIES AND REPLIES.

ED. REPORTER.—In reply to T. A B's question in your issue of February 19th, concerning the weight of Edward H. Rulloff's brain, the following extract from a sketch of his life and character, taken from *The Phrenological Journal*, Sept., 1871, will, we trust, be satisfactory:—

"Very soon after the execution of this singular man, his head was taken by certain authorized physicians of Binghamton, and dissected. The brain was found to weigh fifty-nine ounces, being nine and a half or ten ounces heavier than the average weight. The heaviest brain on record is that of Cuvier, the celebrated French naturalist, which is given by some authorities at sixty-five ounces." JONATHAN FAUST, M.D.

Zieglersville, Pa.

Other correspondents supply the same facts.

Dr. S. J., of N. Y.—The tartrate of morphia has been used, and is well recommended, for hypodermic injections. The proportion is one part to twenty of distilled water. It is said neither to decompose nor deposit crystals. The solution of the acetate rusts the syringe, and that of the bimeconate frequently develops a fungus growth.

MR. EDITOR.—In your issue of Feb. 19th, under Queries and Replies, H. W., of Ohio, relates a case where calomel and chlorate of potassa, given together, resulted in poisoning by corrosive sublimate. His chlorate of potas. was combined with the tinct. of the chloride of iron, which contains free hydrochloric or muriatic acid, and that is where the difficulty was. Chlorate of potas. dissolved in water and given with calomel is entirely harmless. A little medical chemistry is useful. W.

Bloomfield, N. J., Feb. 28, 1881.

MR. EDITOR.—Dr. T. B. F., of Ohio, in the REPORTER of Feb. 26th, asks for suggestions as to the treatment of "an obstinate case of chorea," without giving any reasons for so doing. I would recommend that he use, per rectum, and in suitable amount, chloral hydrate dissolved in milk, and repeat every twelve hours. I would ask that he report success or failure in the REPORTER. H. L. HORTON, M.D.

167th street, New York.

MARRIAGES.

HAYNES—MOORE.—On Feb. 18, by the Rev. Jas. Millett, Ruth A., daughter of J. Moore, and W. H. Haynes, M.D., both of New York.

LANGDON-LUTES.—At the residence of the bride's mother, Medford, N. J., on Thursday, Feb. 24, by the Rev. George R. Snyder, Charles H. Langdon, M.D., of Poughkeepsie, N. Y., and Emma Louise, daughter of the late Elwood Lutes.

SMITH—HAGAN.—In Atlantic City, on February 10, 1881, by Rev. J. J. Fedigan, Dr. Mark L Smith, of Philadelphia, and Katie A. Hagan, daughter of John Hagan, Esq., of Atlantic City.

DEATHS.

COMFORT.—On February 9, 1881, near Wyoming, Minn., Dr. J. W. Comfort, formerly of this city, aged 70 years.

HART.—In this city, Feb. 19, 1881, Harry C. Hart, M.D., in his 53d year.

IRVING.—At West Bergen, N. J., on February 22, Dr. John B. Irving, of Charleston, S. C., in his 81st year.

SCHMIDT.—In New York, on Tuesday, February 22d, D. Webster Schmidt, M.D, in the 48th year of his age, son of the late John W. Schmidt, M.D., of Charleston, S. C.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat. according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O	
Quinidia do	15 "	20	24	2	2	
Cinchonidia do	15 "	C	H	N	O	
Cinchonia do	15 "	20	24	2		
Chinoidine Purified,	30 "					

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

LOCAL ŒDEMA.

Delivered at the Hospital of the University of Pennsylvania, April 27, 1880,

BY WM. PEPPER, M.D.,

Professor of Clinical Medicine in the University of Pennsylvania.

Reported by William H. Morrison, M.D.

Œdema of one Leg from the Pressure of a Truss.

Gentlemen:—Here are two cases, one of which presents points of particular interest, but the other is of rather a common type. They are both instances of swelling of single members. In one case the leg, in the other the arm. The term œdema, or effusion into the subcutaneous connective tissue, is applied to all cases in which swelling of a part pits on pressure. Of course, I except those cases in which there is manifest inflammation. You know that inflammation presents among its local signs swelling of the part, redness, heat and swelling being the distinguishing features of inflammation. There is often present in inflammation a swelling that pits on pressure; to this the term inflammatory œdema is applied; but when we speak of œdema simply, it is understood that there is simply an effusion of liquid into the subcutaneous tissue, pitting on pressure.

The distribution of œdema varies greatly, sometimes being over the whole body, at other times localized to a single member, or even to a portion of a single member. The matter effused also varies greatly; in a typical case of simple œdema the matter effused is the serum of the blood. If the distention is very great, so that the skin appears to be on the point of bursting, the part may feel tense and elastic, and not pit much, but, as a rule, the amount of the effusion is not so great. In other cases we find that the matter effused is not merely serum, but is mixed with more or less of a fibrinous element. This fibrinous matter, which, to some extent, coagulates in the tissues, may become so great as to give rise to marked hardness; in such cases, pitting is very slightly marked. Cases of this kind are especially noticed where there is some inflammatory action going on, while cases of serous œdema, as a rule, occur where there is some obstruction to the circulation.

Such being the case, we should expect to find a great many causes for œdema. One of the most common causes is organic disease of the heart, causing obstruction of the general venous circulation, congestion and œdema. It is customary to say that this œdema generally begins at the feet and extends upward.

Another frequent cause of œdema is organic disease of the kidney. Among the most common symptoms of the different forms of so-called Bright's disease is œdema. This affects not only the legs but also the general surface of the body. Disease of the heart first causes swelling of the legs, and it is not until the later stages of the disease are reached that the œdema affects the upper part of the body; but in Bright's disease we have the upper parts of the body affected before the lower.

Then, again, we find œdema affecting both legs. Among the causes that give rise to this is anæmia, where the blood is watery and the power of the heart is lessened. Here we have the blood settling in the legs, and œdema occurring, particularly toward evening.

Again, we have œdema that does not even affect both legs, but only one. Here we have a marked illustration.

In this case the swelling is limited to the left leg. You can see at a glance that the left leg is much larger than the right. There is, perhaps, a trace of œdema in the right leg, but it is very slight. One of the most reliable ways of telling whether there is œdema or not, is to feel for the malleoli of the tibia and fibula. If there is no œdema they are sharply cut, but if there is œdema they cannot be felt so plainly. Another good plan is to press over the spine of the tibia. This shows a little œdema of the right leg. The other leg is distinctly œdematous, and pitting distinctly on pressure.

We have then a local œdema, which extends to the knee and up the thigh.

Now, what are the causes of unilateral œdema? We should expect to find that it is not due to a central cause. He has no heart disease. If it came from heart disease, we should expect to find both legs affected. There is no albumen in the urine. If it were due to kidney disease, we should find the upper part of the body also involved. It is very rare that a central cause gives rise to a unilateral œdema; it never occurs unless there is some local cause affecting one leg more than the other.

We then approach the part affected, and determine if there is any special local cause favoring this swelling. We notice immediately that the skin is discolored on both sides, discolored in the way you find it when there has been long standing congestion and chronic eczema. Here is the scar of what appears to have been a varicose ulcer. We see distended veins on the right side, to some extent, but they are more marked on the left. There is a varicose condition of the small veins particularly; the large ones do not appear to be much distended.

Going further, following the course of the veins, I examine the groin, and I find that this man has a left femoral hernia, for which he wears a truss. The truss has a very powerful spring, and the pad, which is very long, is so placed that, as you can see at a glance, it bears with great force directly upon the course of the femoral vein. There can be no doubt but that we have here the explanation of the œdema of this man's leg.

There is a varicose condition of the small vessels on both sides, but this is not marked enough on either side to cause much trouble. Here we have had a local obstruction to the blood passing through the femoral vein; this has caused passive congestion and œdema.

You will often find local œdema caused by mechanical pressure applied in curious ways. A too tight garter will often cause œdema of the leg. I have seen a case of œdema of the brow and face, caused by wearing too tight a hat. This œdema had been supposed to be due to some local condition of the tissues.

Œdema of one Arm from Inflammation of the Vein.

Among other causes of obstruction to the return of the blood, is obliteration of the vein, not from pressure, but from disease of the vein itself; especially does this come from the formation of a clot, a thrombus. The instances where we have œdema from thrombus and obliteration of the vein are very numerous. Œdema from this cause is not at all uncommon in cases where the circulation is very feeble, as in phthisis. It is not rare to find a patient with phthisis complaining of swelling of one leg. You immediately examine the urine, fearing that albuminoid degeneration of the kidney has commenced; but the urine contains no albumen, and careful examination shows that the œdema is due to a thrombus forming in the vein.

You meet with this condition in other parts of the body, depending, remember, not upon a clot of blood carried from the heart, an embolus, but depending upon a clot formed in the vein.

Now, mixed up with this question of thrombosis is the subject of inflammation of the coats of the veins, or phlebitis, and we have an illustration of this condition in the so-called milk leg of childbed or phlegmasia alba dolens. It is a local œdema associated with inflammation of the femoral veins. This condition is most frequently met with affecting the femoral vein. It is not limited to women in childbed. It is a common enough accident after typhoid fever. It may occur wherever there is any irritative action going on in the pelvic region. In childbed it is the change going on in the uterus; in typhoid fever, it is the ulcers about the ileo-cæcal valve. The inflammation extends to the sheaf of the iliac or femoral veins, and sets on foot a phlebitis, this passes downward, a clot is formed, obstructing the vessel and œdema is the result. Less commonly, you meet with a similar condition of phlebitis in other parts of the body.

While it is true that the vein is chiefly affected in phlegmasia alba dolens, the œdema is not entirely due to venous congestion. There is also an element of lymphatic trouble; the lymphatics that run along the course of the vein are also inflamed, and we have a lymphadenitis associated with the phlebitis. The matter effused is not only serum,

but there is also a plastic matter from the lymphatics, and the œdema is harder and less doughy than in the simple form.

This man presents himself complaining of a local swelling of the right arm. On examination we find no swelling of the left side, but on the right side you observe that the arm is greatly swollen. The hand is distended and purplish, and when I press it here over the loose connective tissue, it pits. The forearm and arm are also distended. There is also a venous hue, which extends to the shoulder; the shoulder is swollen, and this extends slightly to the pectoral region. The fold of the axilla is partly obliterated; when I press over the pectoral and upper mammary regions, I feel that the tissues are in this œdematous state. There is a little fullness over the scapular region; this does not feel like the œdema of which I have been speaking, *i. e.*, from venous obstruction. It is more firm, more waxy in its feel, as though the tissues were infiltrated with something more plastic than water.

What could give rise to this? There is no cardiac or renal trouble. Any suspicion of such a cause would be removed by the local character of the œdema. We must look for some local cause.

He says that it has existed for seven or eight months, and that it followed a blow on the left side.

Let us see if we can find any local pressure obstructing the vein. Where should we look for it? First in the chest. One of the most common causes of œdema limited to the arm is the presence of a solid tumor in the chest, pressing upon the veins as they return the blood from the arm. Enlargement of the bronchial glands will sometimes cause œdema of the arm. I shall, therefore, first call your attention to the physical signs. He moves his chest well. He has no cough or shortness of breath. On percussion, the resonance over the left side is good, but at the apex of the right lung, probably owing to the thickness of the tissues, the resonance is not quite as good. There is no approach to flatness; simply a little elevation of pitch. There is no flatness anywhere. On auscultation, I hear no râles; the respiration is a little blowing at the right apex, but there is nowhere any evidence of serious disease which would cause this condition. In this hurried examination I find no solid tumor.

In addition to solid tumors, an aneurism of the arch of the aorta may press upon the veins at their entrance into the chest, so as to cause œdema, but examination shows no aneurismal tumor.

Let us see if we can find any evidence of this obstruction causing enlargement of collateral vessels. You see at once that we can. I would ask your particular attention to these enlarged capillaries, forming a zone around the base of the thorax, more marked on the right side. This is a very characteristic evidence of obstruction to the passage of the blood into the vena cava. I have noticed this condition quite constantly in intra-thoracic tumors. I should not like to say positively that there is no intra-thoracic tumor until I have gone over the case more carefully.

Secondly, tumors in the axilla may cause mechanical pressure, but there is no such formation here.

Lastly, instead of having mechanical pressure in the chest or axilla obstructing the return of the blood, we may have inflammation of the sheaf of the vein, and perhaps of the lymphatics, causing phlebitis and obliteration of the vein. This would be phlegmasia alba dolens of the arm. In cases where the trouble is in the groin, you will sometimes be able to feel the femoral vein as a hard cord, tender to the touch. I search here to see if I can find any evidence that the brachial or axillary veins have been turned into solid cords, but I detect no change. Pressure does not cause pain; and yet there can be no doubt but that we have to deal with occlusion of the brachial vein, but the occlusion is further in, and affects the vein after it becomes subclavian. If it were not so, we would not have this distention of the capillaries at the base of the chest.

We may, therefore, pretty confidently assert that this man is suffering from occlusion of the subclavian vein, which prevents the passage of blood into the vena cava, and has thus caused œdema. You will notice that this has appeared to come on in immediate sequence to a blow on the chest, and it is quite probable that at the time there was a sudden wrench, inflammation of the vein was set up, which has run on and has been followed by thrombosis.

Now, as to the results, prognosis and treatment. Of course, the prognosis depends entirely upon the cause. If there is a solid tumor in the thorax, the œdema is only of secondary importance: thus if there is a sarcoma in the chest, pressing on the vein, the œdema is only a symptom, and the prognosis is, of course, unfavorable. On the other hand, failing to find anything of this kind, the prognosis is, as a rule, favorable, so far as concerns the ultimate restoration of the part, but it is uncertain as to the length of time that will be required. Although the part may be

restored to usefulness, it frequently happens that it remains permanently enlarged. I have frequently seen in women who have suffered from milk leg, one leg three-fourths of an inch thicker than the other. Sometimes even after the part appears to be well, there is a sense of weight, clumsiness in the limb, and a tendency to get tired sooner than the other, showing that the collateral circulation does not perfectly return the blood from the part. The treatment is a matter of some importance. Of course, time is the chief element. The part should be kept at rest, the inflammation checked and prevented from extending, and time be allowed either for the clot to be absorbed or the restoration of the circulation by the enlargement of the capillaries. Occasionally a clot becomes absorbed and a channel is formed through its centre, but in other cases the affection of the coats of the vein and the density of the clot is such that it never undergoes this channeling process, but remains as a solid white cord.

The length of time required for the enlargement of the capillaries varies with the extent of the clot and the abundance of the collateral branches. In the thigh the circulation is restored comparatively soon, but in the arm I fear that it will take a long time.

Rest of the part should be insisted on. Counter-irritation over the part by the repeated application of small blisters, or by the repeated use of a weak solution of croton oil and iodine, should be practiced.

I do not know that drugs exert a very great influence over the absorption or organization of these clots, and certainly no drug should be given which would in any way interfere with the digestion. Where a patient is weak, as after childbirth or typhoid fever, a tonic treatment is indicated. Possibly iodide of potassium might do some good, if the clots are very firm. Bandages of the parts and frictions are of service, but must not be used until late in the course of the trouble, for the reason that if the clot is detached there is danger of a serious result ensuing. You can easily understand this. Suppose a clot in the femoral vein is detached ; it is carried into the right side of the heart, and thence into the pulmonary artery, causing embolism of the pulmonary artery. It is to this cause that the sudden deaths after childbirth are often due. The large uterine sinuses are filled with clots ; one of these becomes detached, is carried to the right side of the heart, is pumped into the pulmonary artery, and death results. I have seen death in the same way after phlegmasia alba dolens in typhoid fever. I should especially insist that there should be no rubbing of the part. Later, when you are satisfied that the organization of the clot is finished and there is no danger of detaching it, proper bandaging is useful.

Communications.

OBSERVATIONS ON VENESECTION.

BY G. W. GARRISON, M.D.
Read before the Licking County, O., Medical Society.

* * * I don't wish to be understood as opposed to any of the now popular arterial sedatives, but I do most unqualifiedly denounce as the first in order in all congestive inflammatory troubles, those agents, where we have congestion with inflammation of an organ of a sthenic type. But bleeding, systemically or locally, together with other adjuvants, as fomentations or sinapisms, etc., should hold the first place; after trying this plan, you may consider the propriety of anodynes and sedatives, as the next best step.

Physiologically, bleeding affects functionally every organ of the body, proving its great utility in all congestive conditions or diseases of a sthenic type in plethoric subjects, while local bleeding only acts revulsively, unless carried sufficiently far enough to affect the general system. Bleeding promotes absorption, at the same time blunts the functions of all the other organs of the body not concerned in the constructive metamorphosis of the system. This is apparent in congestion with local hyperæmia, as after bleeding the absorbents are set to work at once to remove the engorged gland, and it will be but a short time until all evidence of congestion or local stasis will be dispelled. Bleeding lessens the fibrin of the blood, as well as the salts and globules, but increases the water.

Therapy.—The therapeutical effect of bleeding in plethoric conditions is largely mechanical, and the remedy would at once suggest itself in congestion of the lungs, when oxidation of the blood, you all know, has become impeded, owing to local stasis on the venous side of the circulation and rapid influx of blood on the arterial ; then to open the median basilic vein in the arm and abstract, say 20 to 30 ounces of blood from the circulating fluid, there would be a reversing (somewhat) the order of things within the parenchyma of the lung, for on the arterial (or systemic circulation) the vis a tergo would be lessened, and vascular tension relaxed, and on the venous, absorption and clearing up of the pulmonary tissue would be inaugurated and repair would rapidly follow as a natural consequence.

The same course of treatment might be pursued in apoplectic forms of congestion of the brain, in which danger would be averted by a generous bleeding, thereby relieving strain on the cerebral arteries. Again, in puerperal eclampsia, a disease always attended with evidences of congestion of the brain, how happily a free bleeding, followed with some other adjuvant, like chloroform inhalation, speedily acts in cutting short those frightful cases. In endocarditis, which is generally accompanied by overdistention of blood on the right side of the heart, the mechanical and remedial effect of bleeding will be very marked and decided. In acute pleuritis, peritonitis, and neuralgias with congestion, the abstraction of blood will greatly relieve the pain and promote quietude, almost like magic. So I might enumerate other diseases where depletion would be advisable, but will not tax your patience further, only by giving a few suggestions in reference to the practice of scarifying, and cupping, and leeching; and after a short description, will report a few cases, as at first intimated.

The propriety of cups and leeches is for their local and revulsive effect (as before remarked), as it would require too much waste of time and torture of the patient to carry this sort of a procedure far enough to affect the general circulating fluid, to make a systemic impression, as phlebotomy and arteriotomy, etc. Leeches are not very easily kept here, and especially among country practitioners; and if they were, I much prefer cups, as their effects are greater and more decided, except in a few instances where cups, owing to the locality of the body, could not be used or applied, as to the neck in tonsilitis, conjunctivitis, orchitis, otitis, etc. Then in perityphilitis, myelitis, nephritis, gastritis, and hepatitis, etc., cupping seems to be a very rational course to pursue at the onset, and oftentimes the remedy par excellence, and none other required in some cases. In the application of cups to a patient it is not necessary to stop at one or two at a single operation; you may use half a dozen at once; and the same way with leeches; use enough to produce the desired effect as speedily as possible.

REPORT OF CASES.

Case. 1.—Mrs. G , in her third confinement (the two previous she had puerperal convulsions); when the child's head began to engage in the superior strait, symptoms of a very suspicious character were evident; at first, pain in the head, bright lights with strange sounds in the ears, pulse very full, and the rhythm of the heart's action could be felt at the fingers' ends. I corded the arm and bled thirty ounces, which answered every indication in the case. Labor proceeded interruptedly for an hour or two, resulting in the birth of a vigorous boy, and the mother had no untoward symptoms to follow.

Second.—Six cases, consecutively, of puerperal eclampsia: Mrs. K. and P., of Chatham, Mrs. H. and G., of Hunt's, Mrs. L. and B., of Utica. Three of these were primiparæ and three multiparæ. Two had convulsions before labor and four after labor. These cases were all bled freely, and recovered.

Third.—Hysterical patients. I have had six or eight of these cases, and bleeding seems to be the best and surest way to scare them out of their whimsical notions.

Fourth.—Pleuritis. Mr. H had a severe attack of pleurisy, rendering respiration quite difficult. I bled him thirty ounces; when relief was speedy.

Fifth.—Otalgia in an unmarried lady, age 35 years. In her case I labored and prescribed for about four hours, using hypodermic injections of morphia and hot applications to the ear and temporal region, and also dropped warm water in the ear, in which I had dissolved morphia, and as time passed, my patient was becoming more miserable. I finally bled her from the arm, some twenty ounces, and the effects were gratifying to a tortured patient, and I assure you that the doctor felt relieved. But in all of my subcutaneous administrations of morphia I failed to discover any of its physiological effects. The pain or neuralgia did not return.

Sixth.—Mr. F. had an attack of gastralgia. I was called to see him thirty-six hours afterward, in consultation with Dr. McKelvy. Upon examination of the case, and the doctor telling me what he was doing, I could only say that the treatment was orthodox, and suggested its continuance; at the same time I assured the patient that relief would certainly come soon, and returned home. In about four hours was sent for in great haste (and the other doctor discharged from the case), and informed that Mr. F.'s cramps were worse than ever. When I arrived I found him doubled up like a dog in his kennel of a cold night. I immediately bled him from the arm, sixteen to twenty ounces, as everything was favorable for such treatment. I stayed with him for some hours afterward, and the pain did not return. I gave him ¼ grain of morphia, hypodermically, two hours after venesection, and within thirty minutes he began to talk at random and would scratch his nose, and, in fact, itched all over, for the first time, proving again that all the

morphia which Dr. McKelvy had given him was not absorbed; but when the system was properly prepared by bleeding, promptly the function of absorption was restored.

To conclude: in the extremes of life, *i. e.*, the very young and aged persons, I would not advise systemic bleeding; for, recall to mind, the coats of the arteries in the old are undergoing calcareous metamorphosis, thereby rendering their elasticity imperfect; while in the young the depletion by blood-letting seems to be too much of a shock to their nervous system; as the momentary anæmia produced in the phlegmatic adult by venesection, in children the effect is still greater, producing a nervous shock or collapse. In conclusion: if I have given any light, either clinically or otherwise, upon the present occasion, can we not restore the lancet to its proper place in our therapeutical remedies?

RHEUMATISM; PATHOLOGY AND TREATMENT.

BY FRED. HORNER, JR., M.D.,
Of Salem, Va.

Acute rheumatism is usually marked by severe pain in one or more of the large joints of the extremities, rigors, hot skin and fever, pulse 120, with gastric and nervous derangement and headache, sometimes amounting to active delirium. A French humorist thus describes the pain: "Place your joint in a vise, and screw the vise until you can endure it no longer; that represents rheumatism." The disease is universal in cold climates, among people exposed to the weather; seamen on board ship, merchant and war vessels, contract it by sleeping on wet decks. In the tropics I have known sailors, during a "Norther," to be taken down with rheumatism. Naval captains will not be persuaded to the contrary that the orthodox custom of washing down decks during wet and cold weather is anti-hygienic. The subject of rheumatism may have premonitory symptoms for years previous to the occurrence of a serious illness, owing to the existence in the blood, from hereditary constitution, of noxious elements, the lithates, oxalates, ammonia, lime, and uric acid, constituting a true "materies morbi." Then occurs sub-acute inflammation of the neurilemma and of the fibrous, serous and synovial tissues; the patient is subject to neuralgia, headache, and attacks of gravel, usually occurring in the autumn or spring months, when the symptoms are aggravated by the prevalence of easterly winds, barometric changes, and excess of electricity in the atmosphere.

The urine, when examined, has an acid reaction, and deposits either lithates, which are of brickdust color, resembling Cayenne pepper, or oxalates, that have the consistence and color of mortar; the blood is so highly charged with uric acid as to affect the nervous substance of the brain. In one example the general circulation was so deranged that the tongue was swollen to an enormous size; the fasciæ of the muscles of the abdomen and the diaphragm were affected with cramps, accompanied by delirium, loss of consciousness, and dysphagia. In the fibrous form of rheumatism the fever is usually the highest, the tongue is thickly furred, the pulse is full and bounding, there are profuse acid perspirations, and the urine is high colored and deposits a sediment consisting of the urates mixed with free uric acid; the kidneys fail to perform their function, and the urea which is not eliminated accumulates in the system and true blood poisoning follows. When these symptoms are violent, the tendency of the inflammation to attack the heart is great. Then effusion of lymph into the pericardium occurs, and occasionally in the interstices of the semilunar valves. The membranes of the brain and the brain itself may also suffer, causing intense pain, coma, and even death.

Treatment.—This embraces the continued use of mild purgatives, anodynes, alteratives and local applications. Pil. hydrarg., chlorid. and ol ricini are to be preferred, and should be repeated if required. 2d, pulv. opii co., gr. vj, at night, every three hours, to induce sleep and diaphoresis; and 3d, solutio salicylate of soda, ℥ ss every three hours, until the fever is subdued. The following formula then may be given:—

℞.	Solutio. protiod. potass.,	f. ℥ j
	Vini colchici,	gtt. xxv.

Ter in die.

The prescription to be continued for six weeks; the patient should be kept in bed or confined to a well warmed apartment, be clad either in woolen, silk or fur during the winter months, and warned against premature exposure to the weather. Insulation by the use of glass supports at the four corners of the bed is recommended; also, the various forms of metallic rings, plates etc., and electro-galvanic belts, by which a current of electricity is applied conveniently and constantly to any part of the body. The scriptural commendation to anoint the body, for example, with cold cream or sweet oil, also comes in well, especially after bathing; the unctuous substance is a non-conductor, and, besides, is promotive of a health-

ful condition of the skin and cutaneous nerves. As to local applications, baths of water as hot as can be borne, for the loins, feet and even head, when the occipito frontalis and fifth pair of nerves of the face are the seat of pain, may be used with great advantage also; pure chloroform applied to the surface, cloths steeped in strong hop tea, will also avail, especially in spasm of the abdominal muscles and diaphragm. The patient may be allowed a generous diet, and lemonade *ad libitum*. It may be added that I know of nothing comparable to Horsford's Acid Phosphate, to relieve the indigestion and so-called sick-headache and mental depression incident to certain stages of rheumatism; and also the thermal alkaline waters of Vichy, Baden Baden, and the Hot Springs of Virginia. In the language of Mark Twain, many patients, after a six weeks' or three months' sojourn and trial of the baths and these mineral waters, leave, and "cordially declare Vichy and Baden Baden are welcome to the legacy of their rheumatism." The late General Robert E. Lee, a short time before his death, bore testimony to the virtues of the thermal and mineral waters of the White Sulphur and Hot Springs of Virginia, which he affirmed had entirely cured him of severe rheumatism, contracted during his eventful campaigns. This class of patients who can afford the expense will do well to seek a residence in Southern or tropical latitudes, where extremes of weather, electrical and barometric changes, are never felt, especially our easterly winds, which have ever intensified the sufferings of the rheumatic.

Among the various methods of treatment which have been suggested of late years by eminent physicians, for the cure of rheumatism, may be mentioned briefly that of Prof. J. M. Da Costa, and published in the Reports of the Pennsylvania Hospital for 1869. His article on the therapeutics of acute rheumatism is based on a series of cases treated with bromide of ammonia, in ten or fifteen grain doses, every two or three hours. The remedy, Dr. Da Costa claims, is especially useful for "patients troubled with great restlessness and pain during acute rheumatic fever, and, on the whole, the results are favorable as regards the prevention of cardiac disease, particularly of endocarditis; this bromide salt has a sedative action on the nervous system and circulation, partly as an eliminative and particularly as a diuretic, though in chronic rheumatism bromide of ammonia is decidedly inferior to the iodide of potassium."

In England, the practice recommended by Todd, who has published a standard treatise on Acute Diseases, is generally adopted. The author assumes that "rheumatic fever is a state of high febrile excitement, induced by the accumulation of a peculiar morbid product, or materies morbi, in the circulation, with symptoms merely caused by certain local derangements, produced at those points whence elimination from the system is taking place. His treatment by elimination is to give the patient an alkaline mixture of bicarbonate of potassium, a scruple or half drachm; nitrate of potassium, ten grains; pill opii or Dover's powder, at night, and to envelop the limbs in soft cotton wool, covered in carefully with a sheet of oiled silk."

OLEATE OF MERCURY.

BY A. HENRIQUES DE YOUNG, M.D.
Read before the James Aitken Meigs Med. Association, of Philadelphia.

I wish to call your attention in this brief paper to a remedy which I deem a valuable addition to our materia medica; to wit, *oleate of mercury*.

Oleic acid, according to Fowne, is obtained by the saponification olein, the fluid constituent of most natural fats and fixed oils. The oleate is the result of the combination of the oleate with a base. The article dispensed is a solution of the oleate in oleic acid, the latter combining with mercury, bismuth, zinc, lead, atropia and morphia. They are prepared generally as five or ten per cent. solutions, and with the exception of the oleate of zinc, are liquid.

The first use I ever made of the drug was in a case of tinea decalvans or alopecia areata, if we wish to latinize the condition found. The patient, a young girl of sixteen years, of a consumptive family, though strong and healthy herself, noticed, about five years ago, a white streak in the scalp, devoid of hair and covered with a thin scale. This was immediately followed by bald spots appearing all over the head, until complete baldness was threatened. The spots varied in size from half an inch to two inches in diameter, each covered with a thin scurf, which on being removed, the skin was found very nearly normal, perhaps slightly congested. Each patch was well defined, the hair ending abruptly at the margin. Matting of the hair occurred in the beginning; then it became lustreless and brittle, the ends split, and it fell out. During the course of the disease, and particularly in the commencement, itching and formication greatly troubled the patient. Various remedies were used, mercurials, copper wash, sulphur, sulphurous acid and others, all with no result. The scalp in the meanwhile being shaved and attention paid to

cleanliness. This state of affairs continued for over five years, new hair springing up only to perish again. Nine months ago I examined the patient and directed her to use a five per cent. solution of oleate of mercury. The hair was shaved off and the oleate rubbed well in every day; in the morning the scalp was well cleansed with Castile soap and water, and the oleate again applied. In the course of a month a great change was noticed, the hitherto bald spots became covered with hair. On again prescribing the remedy, I added as a tonic five grains of the alkaloid quiniæ to the ounce. The hair is now jet black, curly and thick, and from three to four inches long. The scalp is entirely free from bald spots, and I consider her cured of a malady alike detrimental to her hair and peace of mind.

The cause of this disease is parasitic, and its seat the hair follicles.

Tilbury Fox, in his work, says the fungus in tinea decalvans is "the microsporon auduoini. The spores are from the $\frac{1}{25000}$ to the $\frac{1}{5000}$ of an inch, the filaments few, wavy and devoid of granules. The fungus is sometimes found in the epithelium at the extending edge of the disease. He believes, however, that it often lodges behind, in the empty follicles, attacking the epithelial structures therein and interfering with the proper re-formation of the hair."

This case is remarkable on account of its duration and for the shortness of the period in which the cure took place. This, I believe, is due to the rapid penetration and action of the oleate, a property not possessed in the same degree by the ordinary ointments.

I have had happy results in a case of indurated acne of the face occurring in a young man without obvious cause. The disease was of three years' standing, the face being dotted with the pustules and nodules of inflammatory deposit in the skin. Seborrhœa was present to such an extent that it made it difficult to grasp the skin. He had been using the following—

℞. Liq. potassæ, ℥j
Aquæ rosæ, ℥iv. M.

and applied it several times a day.

I frequently, with the aid of a bistoury, scarified the skin and let out the stagnated blood and broken down sebum. Under this treatment he improved, but still the indurations remained, and for this I ordered equal parts of a five per cent. solution of oleate of mercury and cosmoline. Under its influence the nodules and indurations disappeared, and he is now cured. I have seen the speedy dissolution of enlarged glands when treated with the oleate of mercury.

Mr. John Marshall, of England, who first introduced the article, recommends it for all parasitic skin diseases. He also uses the oleate of mercury and morphia in superficial inflammations, especially of the joints. Bartholow, in his work on therapeutics, says "the oleate is extremely serviceable in syphilitic indurations, but is not advisable when ulceration exists." He further remarks that it promptly produces the constitutional effects of mercury. In my cases the oleate was used for several months, and no ill effects followed.

Dr. Alder Smith, in the *British Medical Journal*, reports a case of tinea sycosis cured by the constant application of a five per cent. solution of oleate of mercury.

Dr. John V. Shoemaker, in a paper, urges its use in eczema, psoriasis, pityriasis, erythema, and herpetic eruptions. He found it an invaluable application for general thinning and loss of hair, and employed the oleate of atropia in arresting the abundant secretion of seborrhœa and in subduing high inflammatory action in some cases of erysipelas. He found in the oleate of bismuth a useful remedy in soothing and relieving the cutaneous irritation of acute specific eruptions, especially scarlatina.

Dr. Shoemaker sums up their advantages as follows: First, they do not decompose, like the ordinary ointments, and act as irritants to the skin. Further, oleic acid possesses absorbent and solvent powers that are more active than the bases of ointments. And lastly, they, being liquid, are better suited for application over the scalp, beard, axillary and pubic regions, as they do not mat together the hair.

Hospital Reports.

JEFFERSON MEDICAL COLL. HOSPITAL.

SERVICE OF PROF. WM. THOMSON.

Reported by H. F. Hansell, A.M., M.D.

Two Cases of Optico-Ciliary Neurotomy.

The operation of section of the optic and ciliary nerves has recently been brought prominently before the profession as a substitute for enucleation. Its advocates claim for it the therapeutic efficacy of the enucleation without the deformity necessarily resulting from the operation. Not many years ago the only prevention of sympathetic ophthalmia and only cure for sympathetic irritation was removal of the offending eyeball, the unsightliness of the empty orbit being afterward concealed, to a certain degree, by an artificial eye. It needs no argument to prove the superiority, both in a cosmetic and therapeutic point of view, of the natural organ, with its unchanged powers of movement and perfectly nor-

mal aspect, over the artificial substitute, and in that superiority consists the advantage of opticociliary neurotomy over enucleation.

As an "eye disease," sympathetic ophthalmia belongs to the domain of the specialist, but its influence upon the general system is so great that it is not without considerable interest for the non-specialist. Through that curious connection which we call reflex irritation, other and remote organs of the body become involved, and the practitioner, disregarding the diseased eye as the cause of the trouble, seeks its explanation in the nervous system and alimentary canal. He is misled by the headache, sleeplessness, pain in the neck and back, loss of appetite, irritable stomach and utter weakness, symptoms every one of which is dependent upon the diseased eye, and which disappear immediately when the source of irritation is removed.

Case 1.—Miss S. H., aged 43, after variola at ten years of age, suffered from corneal ulcers, which left her with diminished vision. No further trouble until three months ago, when left eye was inflamed, painful, and gradually lost its power of sight. From the day of admission to the hospital until the operation, one week, the condition of the patient was deplorable. She was so weak that she had not the power to sit up in bed without support; suffered from a stomach so irritable that she was unable to retain food more than a few minutes after it was swallowed, and pain in epigastrium—symptoms strongly suggestive of organic lesion—diffused and severe headache, and was nervous and despondent.

Left eye: Constant pain, increased in pressure over ciliary region, without, however, particularly tender spots; anterior chamber shallow; iris faded in color, much congested and firmly bound down by posterior synechiæ; adventitious membrane occluding pupil; perception of light but no vision. Tension slightly increased. No reflex.

Right eye: Sharp pain at irregular intervals, for *three months*, with slowly decreasing sight; cornea clear; anterior chamber normal; lower two-thirds of pupilliary margin of iris adherent to capsule, (evidently an old iritis). V. $\frac{10}{cc}$. Snellen H_4 at 8″. Fundus normal. Tension normal, refraction myopic; slight pain on pressure.

Case 2.—David Fisher, aged 29, three years ago received gunshot wound in left eye, resulting in total blindness. Since has had no trouble, excepting loss of vision, until two weeks ago, when eye became seat of severe pain; on admittance, general health excellent.

Left eye: Cicatrix in centre of cornea, probably entrance point of shot; posterior synechiæ, ciliary and conjunctival injection. Tension 2. Right eye V. $\frac{20}{xx}$ and normal in every respect.

The operation was performed in the amphitheatre of the Jefferson Medical College Hospital, before the class, by the Professor of Ophthalmology, Wm. Thomson, M.D.

The lids being separated by the elevator, the operator divided the conjunctiva and Fenon's capsule, between insertion of external rectus and corneal border, carrying cut well toward insertions of inferior and superior recti, as in Arlt's operation for enucleation. Then the external rectus was caught on strabismus hook, and brought plainly into view; but before division a catgut ligature, armed at each end with a needle, was passed into the conjunctiva and muscle, about four mm. from its insertion. Its division was made two mm. from suture, thus leaving on bulbus a tendinous stump, which was afterward used for two purposes, as a firm point of fixation for forceps during manipulations, and at the close of the operation to give attachment to the suture. The divided muscle was held out of the way by an assistant, by means of the two ends of the thread. The next procedure was careful division of optic and ciliary nerves, by repeated forward and cutting movements of the scissors. The final steps were sewing together the external rectus, cutting ligature close to knot, and replacing lids over somewhat protruded eyeballs. The after-treatment was cold water dressing and pressure bandage.

The two operations differ in no particular, excepting in the second case the hemorrhage was slighter and consequent protrusion less.

Immediate Results.—First case, anæsthesia of cornea, present on first day. Considerable pain and ecchymosis of lids, giving rise to analogous condition on unoperated lids. A striking instance of sympathetic irritation. The pain in right, which before the operation had been the source of much distress, disappeared in twenty-four hours, and the sight improved greatly, the patient being able to read Snellen $1\frac{1}{2}$, having previously read Snellen H_4. Some adhesions which before were unyielding to atropia were now torn off.

The effect of the operation upon the severe symptoms from which the patient had suffered was remarkable. Within a few hours the improvement in her condition was manifest; headache gone, stomach no longer irritable, pain in epigastrium subsided, appetite improved, and on the third day her strength had so increased that she was able to leave her room and present herself at the clinic. The nervous irritability and despondency had entirely disappeared, and the patient felt she had obtained a new lease of life.

Case 2.—Total anæsthesia of cornea in less than twenty-four hours, the patient being unconscious when cornea was roughly touched with end of match stick. Slighter ecchymosis of lids than in first case, and no pain in eyeball—conditions which may fairly be attributed to his much better general health. On the second day, patient, feeling so well, left the hospital and has not since returned, so that further detail of the results is impossible.

The channel or channels through which the irritation from a diseased eye is communicated to its healthy fellow, has been for the past thirty years a matter of controversy. It is impossible, of course, within the limits of this paper, to discuss the arguments which have been deduced in favor of one or another theory, and it would be foreign to the subject, as they interest us only so far as they have a distinct bearing upon the operation. As early as 1844, Mackenzie refers to the possibility that all three hypotheses might be correct: the advancement of the inflammation through the vessels of the circle of Willis, through the ciliary nerves and through the retina and optic nerve. The progress of our knowledge

since his time is expressed by Mauthner (*Sympathetischen Augenleiden*, 1879, thus: "As to the nature and manner of the conveyance of sympathetic inflammation we know not much better than he (Mackenzie)." Later, Arlt declared, "whether in such cases the optic nerve (*e. g.*, its neurilemma, as far as the chiasm) is the active agent, or the nervous trigeminus and sympatheticus (ciliary nerves), in the present state of our knowledge we are not able to decide. The last is the more probable.

In 1857 Graefe said, "In order to arrive at certainty (whether the optic nerve participates in the sympathetic process of amaurosis), I have proposed in similar cases, instead of extirpation of the bulbus, to make section of the nervus opticus. This would have, among other advantages, that of retention of the bulbus. This proposal was, as far as I know, first introduced by Dr. A. Weber, of Darmstadt." In 1866 the modification of his views is apparent by his advocating "extraocular section of the ciliary nerves, in order that the vessels also be divided." The most forcible objection that has been urged against the neurotomy is reunion of the divided ends of the optic and ciliary nerves, and consequent return of sensibility to cornea and ciliary body, with renewed danger of sympathetic ophthalmia. Schœler, one of the greatest advocates of the operation, admits that the divided ends may grow together, but does not admit that such a reunited nerve is capable of conveying sympathetic irritation. Schweigger, in order to overcome the objection, has proposed the removal of a section of the optic nerve, "neurectomy," but although this may lessen the danger of reunion, it does not completely remove it, for the instances are not few which demonstrate that, in other parts of the body, after section of a piece of nerve, 2–3 cm. in length, the divided ends have reunited. The writer believes that equal if not greater certainty may be obtained by sewing forward the orbital portion of the external rectus muscle of the conjunctiva at corneal edge, instead of to the tendon, thus causing inward displacement of bulbus extremity of optic and ciliary nerves. Mauthner in concluding the discussion of the subject, says, "The operation must be further tried and improved before it can with full confidence be substituted for enucleation.

LOUISVILLE COLLEGE HOSPITAL.

SERVICE OF PROF. DUDLEY S. REYNOLDS.

Reported by A. H. KELCH, M.D.

Astigmatism.

CASE 1.—Miss Eddie G, aged 15, a pupil in one of the ward schools. She has suffered since the beginning of the present session, last September, with difficulty in attempting to pursue her studies at night. The family of which she is a member are in humble circumstances, and when she returns home, at two o'clock, her services in the household are needed; she therefore depends, of necessity, upon her ability to study her lessons at night, and this she is now no longer able to do.

Her eyes become red and smarty, feeling as though she had sand in them; presently the tears flow and the letters are so completely obscured that it is no longer possible for her to read. She has become quite nervous and suffers from sick headache, though she is of vigorous growth, well nourished, having a blush on her cheek equal to the best appearance of Hebe or Euphrosene in their palmiest days. She is unable to recognize any of the test letters in Snellen's graded scale at the distance of twenty feet. She should be able to read the bottom line upon the card, if she had normal vision.

She is now, as you observe unable to read at twenty feet what the normal eye would recognize at two hundred feet. She has been using a four grain solution of the sulphate of atropia for about two weeks, and we hope to find her accommodation fully suspended. On placing a positive glass, numbered 10, and which, as you understand, has the power of converging light to a focus at ten inches from the centre of the lens, she reads $\frac{20}{LXX}$. On placing Donders' stenopaeic disc before her right eye and closing the left she sees, when the slit is held vertically before the eye, $\frac{20}{XXX}$, with $+\frac{1}{6}$; reversing the disc so as to allow her to see in the horizontal meridian only, she reads $\frac{20}{XXX}$, and there is no glass in the whole case which will further improve her vision in this meridian. Testing the other eye we find vision in the vertical meridian, without any glass, equal to $\frac{20}{L}$. In the opposite meridian $+\frac{1}{6}$ gives her an equal amount of vision. The vision of this eye cannot be raised above $\frac{20}{L}$, while in the opposite eye she can with some difficulty read $\frac{20}{XXX}$ with $+\frac{1}{6}$. We, therefore, order for her $+\frac{1}{6}$ c ax. 90°. On placing these lenses before her eyes, she reads with great ease and comfort $\frac{20}{XXX}$, and she can make out a few letters in the lower line, which shows that her vision is but little less than normal. The want of perception, or the obtunded sensibility of the retina, is, no doubt, due to the fact that she never yet had light focused in the retinal substance. As she is young, we may reasonably expect that she will, in a short time, be so improved in her powers of perception as to make her vision absolutely normal, with the aid of these cylindrical lenses.

This is an unusual degree of astigmatism; it is extremely rare to find a person with an astigmatism equal to $\frac{1}{6}$, but we have demonstrated that in the right eye it even equals $\frac{1}{4}$. With these glasses, which she is to wear all the time, she will enjoy the power of reading and pursuing her ordinary studies with ease and comfort, after a very brief experience in their use. I confidently expect that she shall no more be tormented by local discomforts in the eye or by the sick headache, and that this nervous agitation will almost immediately vanish.

These cases are by no means rare. They are observed daily in practice, and you are likely to encounter them early in your professional career. You ought to remember that defects of refraction in the eye often give rise to a train of symptoms hitherto attributed to some obscure diseases of the brain, and, by some of the old writers, they were supposed, in many instances, to arise from

some derangement of the uterine function, or from disturbances of the digestive functions.

By the labors of Donders, more than by those of any other one man, the happy solution of this class of difficulties has been reached. However much may be said in opposition to the division of the practice of medicine into specialities, the art of healing has been enriched by the addition of some of the most brilliant triumphs of scientific medicine through the labors of the ophthalmologist. If ophthalmology had done no more than discover the means of relief from these hitherto perplexing disturbances of the nervous system due to errors of refraction, it would be entitled to live forever in the memory of an afflicted world.

Now a word about the manner in which we record defects of refraction. You remember we have registered the acuity of Miss G's vision as being equal to $\frac{20}{xxx}$. It may be asked "why do you employ this irregular fraction, why not reduce it so as to make it read $\frac{2}{3}$?" I answer that in calculating the acuity of vision the distance at which the observation is made is always taken as the enumerator of the fraction whose denominator is represented by what the patient actually sees at that distance. Miss G. sees at twenty feet what she should see at thirty; we register, then, $\frac{20}{xxx}$, which fact the exact acuity of her visual perception. If we reduce the fraction to its simplest form, we might for the time being understand all about the scientific principles involved in the test, but by to-morrow we should most likely forget what the original characters were from whence we obtained this simple fraction. In other words it is the rule, in fact, a principle of science, that in testing the refractive powers of the eye we make use of the distance at which the test is made, always as the enumerator of a fraction whose denominator is represented by the acuity of vision possessed by the eye under examination.

It is therefore readily seen under just what circumstances this result has been obtained, and its actual scientific value may be understood by any person reading the memorandum so taken. Now, for instance, if I test the vision for parallel rays of light in a suspended condition of the accommodation, and find that the patient is able to read without any glass at all $\frac{20}{0}$ and I reduce this fraction to $\frac{1}{3}$, which is its simplest form, it would appear that the patient's visual perception was but $\frac{1}{3}$ of what it should be, when, in fact, it may be absolutely perfect, the difference being that whereas the patient sees perfectly at five inches from the face, being able to recognize objects which are, perhaps, not distinctly visible by the normal eye, he has, by virtue of an excessive power of refraction, an inability to so relax that power as to enable him to unite parallel rays of light. This rule applies with equal force to the hypermetrope and the myope, both of them, perhaps, having normal acuity of perception, and both of them having errors of refraction, which, if the vision be tested at a particular distance, unfavorable to the eye examined, would make it appear that there is some organic deficiency of the visual power. Then, you are to understand that the nature of your test and its value may be known by your strict observance of the rule. When a person says the patient's vision is $\frac{2}{3}$ of normal, you will recognize the statement as coming from an ignorant and incompetent observer; because there are no means of dividing the visual power by such simple fractions.

In making a prescription for spectacles, you should always be particular to state the character of the refracting surfaces of the lenses ordered, in plain mathematical characters, and state what the distance shall be between the centres of the pupils, remembering that the distance between the pupils will be $\frac{1}{8}$ of an inch less when the eyes are directed to near objects, than for distant vision. The amount of curvature in the piece that is to lie upon the nose, as well as the general character of the frame, should be definitely stated. The patient should be made to understand that the optical axes of the lenses and of the eyes before which they are placed should always correspond. That it is seldom possible for the plain frames to be placed with the bows down upon the ears and secure satisfactory relations of the spectacles to the face for reading. The popular styles of what are called eye-glasses are nearly always a source of discomfort to those who wear them; they do great harm, by creating muscular strain, from the want of proper adjustment. Lenses in lorgnette or eye-glass frames can never be made to lie in the same place, and they therefore tax the eyes greatly to overcome this want of harmony in the adjustment of the glasses.

Mrs. M., aged 50, you will remember, was the subject, several weeks ago, of a very painful distention of the right tear sack. She had, years ago, an obstruction in the nasal duct, which was overcome by dilatation with Bowman's probes. The operation was begun by slitting the inferior canaliculus with Weber's knife, followed by the daily passage of Bowman's probes, until all inflammatory symptoms disappeared. The eye remained well for two or three years, when she contracted a nasal catarrh, which, by continuity of structure, extended through the nasal duct into the tear sack, and rekindled a muco-purulent inflammation, which brought her to the clinic a few weeks ago. Examination showed, on her return here, that the inferior canaliculus had become entirely closed; the old stricture at the superior extremity of the nasal duct had again appeared, and the sack was filled with muco-purulent material, the tears overflowing the lid and running down upon the cheek. Now, as it was impossible to pass a probe through the inferior canaliculus, on account of its closure, I enlarged the superior punctatum, and attempted to pass a probe into the nasal duct. I introduced Bowman's probe, No. 4, into the tear sack, without difficulty, but immediately on engaging the orifice of the nasal duct, it met with a firm obstruction, which I was not able to overcome without the employment of what I deemed unwarrantable force. I therefore injected a five-minim solution of carbolic acid to the ounce of water, through an Anel's syringe, into the tear sack, washing out all the morbid accumulations, and the next day renewed the attempt at dilating the stricture in the nasal duct; and so on, from day to day, until finally, on the fourth day, a No. 4 probe passed. The next day No. 2 was the

largest that would pass at first, but by withdrawing this and introducing a grade larger, I was finally able to pass No. 8.

She appeared to recover after this, without further trouble. In two weeks the eye again began to water. She was not in the city at the time, and so did not see me until four or five days later. I then found the stricture in the nasal duct had returned, though there was no morbid matter in the tear sack. I divided the superior canaliulus and persisted in my efforts until a No. 6 Bowman's probe again passed through the stricture in the duct. I introduced then a stylet of silver the size of a No. 6 probe. She wore this until I could have a gold style, with a "shoe-flange" at the upper extremity, constructed for her. This style is seven-eighths of an inch long; I slipped it over a No. 4 Bowman's probe and introduced it through the upper passage into the tear sack, and passed it on into the nasal duct, until the flange was lodged in the slit of the upper canaliculus. I then withdrew the probe, and pressing upon the flange, left the style in the position you now see it. She has now worn it nearly a week, and there is no sign of discomfort, no more overflowing of tears, no more swelling from accumulated matters in the tear sack, and I confidently expect Mrs. M. to remain well for at least a long time to come. I have known persons to wear these gold tubes in the tear passage for a period of twelve years, without suffering inconvenience. There is now a young lady in society, in this city, who has worn one for more than ten years, and if you should meet her, you would not suspect that she had ever had a weeping eye, save that which might have been caused by disappointment in love.

Mrs. C., aged about forty, lives in the eastern part of the city, on Payne street, which runs very near the Newcomb Buchanan distillery, on Bear Grass creek. This is a very sluggish stream, full of organic matter of the most offensive kind, coming from more than a score of pork houses and distilleries situated along its banks. If you were to visit the neighborhood, which is known as "Jerusalem," you would be obliged to hold your nose and employ some rapid method of transit to hasten through the foul section, whose odors, we have been told by a member of our local Board of Health, "Cry to the very heavens," in piteous strains, for some kind of relief to the populace from these death-breeding gases. She has a complicated affection, a blepharitis papillosa of long standing, and now she suffers from acute trachoma. Trachoma, according to Mr. Marston, is an infallible sign of that form of malaria which produces intermittent and remittent types of fever. Trachoma begins in an abnormally rapid proliferation of the connective-tissue-cell contents of the conjunctival membrane, in fact, I may say of mucous membranes generally, as you will often find them in the nasal membrane, in the pharyngeal membrane, where, strangely enough, their presence has led to the absurd term follicular inflammation.

This condition, called trachoma, rarely produces any inflammatory action in the affected membrane. It frequently exists for months in the same membrane without giving rise to anything akin to inflammation, and you will often see it in an otherwise sound structure. The disease presents the appearance of a granulated surface. On closer inspection it is found that the elevations upon the surface are ovoidal in form, seem transparent, amber tinted, and look some what like small eggs, about the size of rice grains, deposited in the substance of the mucous membrane. These ovoidal bodies are the greatly distended connective tissue cells, and when a number of them lie together, present the appearance of gland substance; hence their appearance in certain mucous membranes has given rise to the term "*adenoid tissue development.*" They are veritable neoplasms when found aggregated in large quantities in the mucous membrane. They neither break nor do they shrink in size. No local treatment except mercury in some form has ever been known to hasten their disappearance. They may occur in an inflamed as well as in a healthy mucous membrane.

In Mrs. C's conjunctival membrane, the papillary layer of which has for a long time been hypertrophied, these bodies are now found in the retrotarsal fold, and upon the surface of the globe; a few of them may be seen near the free border of the lid. In fact, they are interspersed along with the hypertrophied papillæ. Her pulse is quick and feeble, her skin cold and clammy, her tongue pale and flaccid, with the prints of her teeth upon its margins. and she complains of quotidian attacks of the headache; she is constipated and has no appetite; she is a poor woman, and earns her living at the wash-tub. Let her have five grains each of calomel and chlorate of potash, immediately, as an aperient, and give her one drachm of quinquinia, divided into twelve powders, one of which she is to take before each meal, until the whole are taken. You observe I make a direct application of the crayon of muriate of ammonia to the everted lid, this with the view of promoting the resorption of plastic material deposited in the papillæ, and without any anticipation of changing the form or character of the trachomatous deposit. She is to have, as a soothing application, a solution of borax (gr. 5–ʒ) a small portion of which may be dropped into the eyes every hour or two, when they feel uncomfortable. We hope by the improvement of her general health from the effects of the quinquinia, that the disease will be abated, and that she will again be able to earn her living. Of course this papillary disease in the eyelids cannot be cured unless she could spare time from her labors, but that is no reason why we should not attempt to alleviate her sufferings.

My friend, Professor Seely, of Cincinnati, has written a great deal in the medical journals, particularly in the Cincinnati *Lancet and Clinic*, during the last few years, on the subject of the local treatment of acute trachoma. He talks about the discharge from the surface, as though it were usually attended by some inflammatory action in the membrane, and he seems to rely entirely, or nearly so, upon local treatment. Now, I quite agree with my friend, as to the damage usually done by caustic applications in this form of disease. I agree, also, that the ointment, which I think he will find was first recommended by Mr. Earnest Hart, editor of the *British Medical Journal*, is a precious thera

peutic agent in the chronic forms of trachoma, complicated by catarrhal or phlyctenular disease. The ointment used is the yellow oxide of mercury, in the proportion of about three grains to the half ounce of glycamil or vaseline. It is very important that the mercury should be thoroughly rubbed with the menstruum, so as to insure a uniform distribution.

I dislike to take issue with my friend, of Cincinnati, but I beg to assure both you and him that my cases of acute trachoma recover quite uniformly without any local treatment whatever, by the bare use of full doses of the sulphate of quinine, always taking the precaution to administer a purgative beforehand. I have the notes of several hundred cases of acute trachoma, many of them treated at this clinic with the sulphate of quinine and without any local treatment, and I think I might with pardonable pride point to the almost uniform result of that treatment. I cannot understand how a disease which every one recognizes as one of the manifestations of marsh miasm, or malaria, as we call it, can be removed by the purely local treatment of its manifestations in the conjunctival membrane, without regard to the general systemic affection, though it may be masked, or of such mild form as scarcely to be recognized.

Medical Societies.

PHILADELPHIA LARYNGOLOGICAL SOCIETY.

A stated meeting of the Society was held at the house of Dr. Jos. B. Potsdamer, 1428 Poplar Street, February 25th, 1881. The meeting was called to order at 8.30 P.M. The President, Dr. Cohen, in the chair. Members present: Drs. Cohen, Smith, Barton, McCracken, Sajous and Potsdamer.

Minutes of last meeting read and approved.

Dr. Cohen described a case of ozæna in a girl at puberty, in which the lower turbinated bones were lost, giving a full view of the middle turbinated bones, and enabling him to examine the entire surface of the diseased process, in a manner absolutely out of question under normal conditions. The doctor stated that this case illustrated the difficulty of properly cleansing the nasal passages, even with a douche.

Dr. Sajous exhibited a case of paralysis of the posterior crico-arytenoid muscles, with thickening of the posterior wall of the pharynx on the right side, shutting out from sight the pyriform sinus on that side. This patient, when he first came under treatment, had very little breathing space, the vocal cords being almost in apposition, but he has improved markedly since, under the influence of increasing doses of iodide of potassium. When this man drinks any liquor his cords become congested, and they are brought nearer together. Electricity has been used without producing spasm, but was of no benefit. Dr. Cohen suggested linear counter-irritation over the region of the pneumogastrics in the neck.

Dr. McCracken then read his paper on Acute Catarrhal Tonsilitis. The doctor stated that he meant by this acute inflammation of the mucous membrane and follicles of the tonsils. He called attention to two forms of the disease, to wit: one in which abscess does not form and the other in which it does.

The subject of tonsilitis was then discussed by the members present. Dr. Cohen stated that in treating these cases if the patient could submit quietly he coated the whole tonsil with solid nitrate of silver.

Dr. Barton exhibited some lozenges for use in catarrhal sore throat, suggested by him to replace the mass long used in the throat clinic of Jefferson Med. Coll. Hospital, and from which the patient broke off, from time to time, as much as was required. He had added powdered rose leaf to the formula, by means of which he has been able to secure a good mass for a lozenge The formula is as follows, to wit:—

℞.	Tr. capsici,		♏ ½	
	Acid. sulphuric. aromat.,		♏ j	
	Confectio. rosæ,			
	Folia. rosæ,	āā	gr. j	M.

Ft. troch. No. j.

It was then decided that the next meeting of the society be held at the house of Dr. Isaac Barton, 128 S. Fifteenth street. The Doctor was appointed essayist of the evening.

On motion adjourned.

Jos. B. Potsdamer, *Secretary, pro tem.*

Sudden Death in Pleuritic Affections.

Dr. Leichtenstern (*Deutsches Archiv für Klin. Medicin.*, Band iv, 4 Heft) discusses a number of cases recorded in medical literature, of pleuritic patients in whom severe syncope and sudden death have occurred, with the view of explaining the causes; and he arrives at the following conclusions. Sudden death or severe attacks of syncope in cases of pleuritic effusion have sometimes their origin in embola of the pulmonary arteries. In other cases, no pulmonary embola exist, but voluminous and far-extending thrombi in the right auricle and ventricle, and in the superior vena cava. The generally prevailing view that left-sided effusion has a greater effect in disturbing the circulation than effusion on the right side, is incorrect. On the contrary, extentensive exudation on the right side causes greater disturbance of the circulation by pressure on the large vessels, and on the right auricle and ventricle than does considerable effusion on the left

side. And the opinion that cases of sudden death and severe syncope are more frequent in left than in right exudation, is contradicted by statistics. Of fifty-two cases, in thirty-one the exudation was on the right side, and in twenty-one on the left. Cases of sudden death, apoplectic attacks in pleuritic effusion, sometimes arise from embolism of an artery of the brain, or its consequences. In a great number of sudden deaths with pleuritic exudation, we are not yet in a position to explain the cause. The fatty degeneration of the muscles of the heart, the anæmia of the brain, and the œdema of the lung, do not suffice for an explanation. To anæmia of the brain as a cause, those cases only can be assigned in which the raising of the sick person from the horizontal position has been followed by severe syncope ending in death. Various causes which sometimes quite interrupt or impede the flow of blood to the left heart, such as a severe paroxysm of coughing, vomiting, lifting heavy burdens, may give rise to a sudden fatal anæmia of the left heart, and secondarily of the brain. The anæmia of the lungs or brain found in many cases is only of secondary importance. It frequently happens, after thoracentesis with aspiration, that an anæmia is induced in the partially distended lung; and this may lead to death by asphyxia. In sudden death, during or immediately or a short time after thoracentesis by aspiration, the cause is anæmia either of the heart or of the brain. In cases in which severe syncope and sudden death are observed during the irrigation of the pleural cavity, the cause is either direct mechanical concussion of the easily exhausted heart by the stream of water thrown in, or shock. The washing out of large empyemic cavities with strong solutions of carbolic acid may cause severe collapse, and perhaps death, due to the rapid absorption of large quantities of the acid.

Iodoform in Chronic Nasal Catarrh.

Dr. H. A. Eberle, of Iowa, writes to the *Michigan Medical News*, of January 10:—

In this State, where catarrh is so prevalent among the people, any remedy that would perform a cure will be hailed with the greatest delight. Iodoform, as a remedy for chronic ulcers, was used quite extensively in the Montreal General Hospital in 1872 to 1876, with such good results as to warrant its trial in private practice. Since that time I have made use of it in very many ways, in the treatment of piles, fissures, granular ulcerations of the uterus, etc., and always with gratifying results.

In view of all its healing properties, I was led to adopt the remedy for the treatment of catarrh, and as I had been a sufferer from the disease in a chronic form for many years, and had used many preparations with varying success and little benefit, I concluded to make use of it in the following manner. First, an ointment is made, thus:

℞.	Iodoform, finely powdered		grs. lx
	Ext. geranium, solid,		grs. x
	Acidi carbolici,		gtt. xv
	Cosmolinæ,	q. s.	℥j. M.

Secondly, bougies are made out of absorbent cotton saturated with the above ointment and simply introduced up the nasal passage as far as necessary at bedtime. These are left in all night and are easily removed in the morning by blowing the nose.

This is repeated for a week or ten days, when the most obstinate case of catarrh will yield to the treatment. Scarcely any other treatment is necessary, except the occasional use of the posterior nasal douche with some cleansing fluid. I usually employ a weak tepid solution of chloride of sodium before introducing the "iodofodized cotton" tent.

Treatment of Chronic Prostatic Enlargement.

Mr. Thos. Smith, surgeon to St. Bartholomew's Hospital, in a recent lecture published in the London *Medical Times and Gazette*, gives the following advice on the above subject:—

Treatment.—Your assistance will rarely be sought in the early stages of this disease; but should you be consulted by an elderly patient suffering from undue frequency or difficulty in micturition, it will always be prudent to make a digital examination through the rectum, to ascertain the condition of the prostate. The examination is best made with the patient lying down on his back. Your finger-nail being filled with soap, and the finger well oiled or greased, it should be introduced very slowly, so as not to excite spasm of the sphincter.

Should you judge that the urinary difficulty is caused by prostatic enlargement, the occasional passage of a full-sized instrument will often relieve the inconvenience, and, if steadily persevered in at regular intervals will generally secure the patient against all the more serious consequences of the disease.

In cases where the difficulty in micturition has gone on to produce an inability to empty the bladder completely, it is of primary importance that at least once in the twenty-four hours the urine should be all drawn off; but in carrying out this plan it is necessary to exercise caution, lest by suddenly emptying a greatly distended bladder you should produce a complete paralysis of the organ, with a loss of the power of voluntary micturition, and cystitis.

As a general rule, if there be not more than one pint of retained urine in the bladder—that is, urine the patient is unable to pass for himself, it may be safely drawn off at once. But if there be more than this of residual urine (and there may be several pints), you should draw it off by installments, taking away a little more each day, until the bladder is completely emptied.

This complete evacuation of the bladder, when once accomplished, should be repeated each day, by means of an instrument, and for the purpose an india-rubber catheter, a bulbous-ended or a Coudé catheter, should, if possible, be used.

By these means, in an early stage of the disease, the patient will generally regain the power of normal micturition, or at all events, if this result be not attained, he will be secure from the worst consequences of the disease.

The treatment may be carried out by the patient himself if you will be at the pains to teach him how to pass an instrument—nowadays a comparatively simple process, owing to the great

improvements in catheters; for you should know that since the introduction of the various forms of soft catheters now in use, the instrumental treatment of prostatic enlargement has lost more than half its terrors and much of its danger.

This large silver prostatic catheter which I now show you—at one time almost the only instrument used in these cases—is truly a formidable weapon, with its long shaft and wide-sweeping curve. It was constructed to ride over the prostate, but in the hands even of experienced surgeons it frequently failed in the performance of its normal functions, and rode under the gland, or through its substance. Used with a strong and steady hand it rarely failed to draw off water. As an instance of its powers in this respect, I may mention a case within my knowledge where a prostatic catheter in the hands of an energetic surgeon drew off some gallons of water, which, however, a post-mortem examination disclosed to have come from the peritoneal cavity.

I will suppose now that you are called upon to treat a patient with retention of urine dependent upon enlarged prostate. The difficulty will usually have come on at night time; the patient will, as a rule, be advanced in years; and the prostate can be felt in the rectum unduly prominent. In such a case let me advise you first to try a flexible red rubber catheter, of full size; it will often find its way round a corner, and through a urethra which would be impervious to a more rigid instrument. This failing, you should try and pass the same catheter with a stout wire stylet reaching two-thirds of the way down the instrument; this gives you more power to push the catheter onwards, and leaves the end flexible, to accommodate itself to the distorted urethra.

Next in order you may try the Coudé catheter, which I show you; then, if necessary, the bulbous French instrument, a gum-elastic, without and with the stylet; and lastly, others failing, a silver instrument.

Whatever instrument you use, let it be a full size; it will go in as easily as a smaller one, and is less likely to damage your patient. Keep the point of the instrument on the upper wall of the urethra; and, above all things, use no force.

After drawing off the water in a case of retention, the patient will, for a time at least, require the regular use of the catheter until he recover his power of voluntary micturition; and should there have been great difficulty in introducing the catheter, I should advise you to tie it in for the first twenty-four hours.

In the subsequent treatment of these cases of prostatic retention, in addition to other troubles, you will often have to contend against an increasing frequency in micturition. The frequent desire to pass water must be resisted as much as possible by the patient, or it will grow upon him. The bladder must be completely emptied, and, if need be, washed out, at regular intervals, and the patient exhorted not only to resist by a strong effort of the will the solicitation of his bladder, but to avoid all sights and associations that are likely to suggest to him the necessity of micturition. With this object in view, you should counsel your patient to keep his catheter and chamber-utensil out of sight; as soon as possible to leave his bed-room during the day; and to occupy his mind by any pursuit which may draw his thoughts away from his urinary necessities.

Ulcerous Endocarditis.

Dr. Barie, quoted in the London *Med. Record*, gives the following case of this disease:—

The patient, a female, had had three children, the last four and a-half months before admission, the labor having been normal and followed by no accidents; the child was strong and healthy; she suckled it. Five or six days before admission she suffered from indisposition, loss of appetite, pain in the back, and slight diarrhœa, but continued at work till the night before admission, when she had an attack of the 'nerves,' with loss of consciousness. On admission there was a little fever (100.7° Fahr.); there was redness, swelling, and pain of the two wrists and the right shoulder. For twelve days there was little change. Suddenly, one day at 3 P. M., the patient was seized with rigors, fever, and nausea; at 5 P. M. the temperature was 104.7° Fahr., pulse 120. She complained of sharp lumbar pains with tingling in the lower limbs; these latter were moved with difficulty, but sensibility was intact. The next day her state was worse; the pain in the wrists was gone, but there was complete paraplegia. On the right, the limb was absolutely inert, cold and cyanosed, with anæsthesia and analgesia from the upper fourth of the thigh downwards; no reflex movements. On the left, the paralysis was less absolute, the cyanosis and coldness less complete, and the alterations of sensibility reached only as high as the lower fourth of the thigh exclusively. There was no pulsation in the arteries of either paralyzed limb; on pressing the abdomen, no arterial pulsation could be felt, but severe pain was produced, which extended from the umbilicus to a little above the pubes, but this was only when pressure was in the middle line. She died six days afterwards; gangrene of the lower extremities had commenced. At the necropsy there were found a thrombus obliterating the mitral orifice, and ulcerative endocarditis of the posterior surface of the left auricle and of the mitral valve, and some atheroma of the aorta, which at the level of its bifurcation was plugged by a fibrinous clot prolonged into the right iliac for 3 centimeters and into the left iliac for 1 centimeter. There were no other coagula; the arteries of the brain were normal. The spinal cord was congested in the lumbar region; it presented no histological alteration, except this congestion.

The Antispasmodic Effects of Alcohol.

In the London *Med. Press and Circular*, January 12th, Dr. Benjamin W. Richardson, equally distinguished as a physiologist, physician and temperance advocate, gives the following case illustrating the use of alcohol as an antispasmodic:—

R. S., clergyman, aged thirty-six, feels weak, memory enfeebled, vertigo, great loss of power in the loins and muscles of the lower extremities, he imagines he must fall. His face is pale; his

extremities are always cold; his bowels constipated; the evacuations of clay-like color, being sometimes firm and hard, and at other times fluid and resembling yeast. The urine, copious and pale, has a sp. gr. of 1.018, but is free of albumen. The respiratory sounds are clear. The pulse is sixty-eight, and the three sphymophonic indications are present, but it is so thin and small it is scarcely perceptible at the wrist. The heart sounds are clear, but with an occasional soft murmur at the base on the right side. The impulse of the heart is intense, and is described by the patient as a "persistent palpitation." In this case I commenced the treatment by carefully regulating the diet and regimen, withdrawing tea, and enjoining less work. As the patient was neither a smoker nor a drinker of alcohol in any form, I encouraged him to maintain abstinence in those respects.

The symptoms in these examples all point to the one deranged condition. There is an irritation, so to speak, extending through the whole of the arterial system, by which the resistance to the flow of blood through the body is impeded. This leads to a temporary impairment of nutrition, and to central nervous exhaustion. In plain terms, there is spasmodic peripheral resistance from an irritation which is felt by the heart itself.

In these cases, if attention be paid to the secretions as a preliminary; if the mind be relieved, as far as is possible, from worry; if daily exercise be enjoined, with early hours for going to bed; and if full quantum of sleep be secured, the symptoms often pass away without other aid; but this is not always the case, and when the phenomena continue, alcohol with amyl nitrite, judiciously administered for a short time, is of signal service.

In the case I have recorded I prescribed first nitro-hydrochloric acid, with tincture of nux vomica and infusion of gentian, together with an alterative. This not succeeding, I prescribed iron and quinine (Easton's syrup). After some few weeks' failure—accepting the case to be one of the class described above—I ordered

℞.	Amyl nitrite,	♏ ij
	Alcohol, sp. gr. .830,	ʒ iij
	Liquid taraxacum,	ʒ ij.

To make a dose to be taken three times a day, in a wineglassful of water, after food.

The result of this treatment was immediate. It was like the result of an experiment. On the visit of the patient to me, a week after the treatment had commenced, the pulse was full and soft, the heart's action was quick, the bowels were acting regularly, the mental activity had greatly improved, the body was of natural temperature and the pulsation was much improved. At first the medicine produced some flushing and throbbing of the temples, but this passed away after two or three days, and in the course of a month the health was quite restored, on which the medicine was withdrawn. For fourteen months this patient has, I find, continued well, remaining still a total abstainer from alcoholic beverages. He is now doing his full share of professional work.

Another class of cases resembling the above is often met with, in which there is dryness as well as coldness of the skin, attended with lepra or psoriasis. In these persons there is, as a rule, a syphilitic history, acquired or inherited. In them the action of the heart is intense, with a feeble pulse and nervous exhaustion. These are benefited by alcohol in properly administered doses. I usually prescribe for an adult in such examples—

℞.	Liquid arsenite of potassa,	♏v
	Pure glycerine,	ʒj
	Alcohol, sp. gr. .830,	ʒ ss
	Distilled water,	ʒj.

To be taken in half a tumbler of water three times a day, after food. In some instances I also add to this prescription two or three minims of the nitrite of amyl, and I have seen recovery, when arsenic alone has failed, commence immediately on the addition of the antispasmodic.

Bladder Drainage in Chronic Cystitis.

In the course of an address before the Medico-Chirurgical Society of Edinburgh, Mr. John Chiem said:—

Let me particularly direct attention to bladder drainage in chronic cystitis. It will, I think, take a most important place in the treatment of that troublesome and common affection. The two great symptoms are frequency of micturition ("irritable bladder"), and excessive quantities of mucus in the urine (catarrh of the bladder). The first symptom is at once relieved by the use of the instrument, and in some cases its use even only during the night gives the patient unspeakable comfort; but in the majority of cases it is best kept in the bladder continuously. The difficulty is the choking of the instrument with mucus; this will be prevented by having a double eye in the catheter, and by raising the bottle night and morning, in order to make a back flow, which clears the instrument. The patient can very soon tell when the flow ceases, and the bottle can then be raised slightly above the level of the patient. At once the plug of mucus is displaced. It is very interesting to observe the effect of rest to the bladder as indicated by the decrease in the quantity of mucus. In one case of perineal fistula, complicated with chronic cystitis, this improvement was very marked. The systole and diastole of the bladder are excessively increased in irritable bladder. No heart would stand such an increase in its pulsations. This, in my opinion, is one of the reasons why chronic cystitis is so intractable, and any means by which we can prevent the periodic rise and fall of the bladder, the incessant unrest of the organ, will always be of the greatest value in relieving inflammation of the viscus. For its value in chronic cystitis alone I would be inclined to recommend a careful trial of bladder drainage. By some means or other let it be carried out; the method matters not. What is important is to come to a conclusion as to the value of the principle involved. Its main value in chronic cystitis, in my opinion, is to give the bladder rest. It acts as a drainage-tube in a wound or in an abscess cavity. It has, however, a value

in urethral fistulæ; in those requiring plastic operations it keeps the wound dry and allows speedy union to take place; in those requiring only that the urine which is abnormally passing along the fistulæ and keeping them open should be prevented from so doing, by being drained off immediately on its entrance into the bladder. *To give the bladder rest* and *to keep the urethra dry*, I know no better means than that which I now advocate. I am not aware that the idea of keeping up a constant suction power which draws off the urine as it drops into the bladder has been previously recommended in surgical practice. It is certainly a very different thing from the use of the catheter tied in and used in the ordinary way. That the means recommended are simple is self evident; they can be applied by any one. That no harm is done to the patient is the result of my experience; that all operations on the urethra are treated more certainly by the use of the apparatus, and that it is of great use in many cases of chronic cystitis, relieving the symptoms in all, and giving permanent relief in others. That the symptoms of chronic catarrh are in some cases very intractable is evident, when we remember that chronic cystitis has been treated by the lithotomy incision, in order simply to rest the bladder.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A very thorough monograph on "Anomalies of Perspiration," is sent us by the author, Dr. J. H. Pooley, of Columbus, Ohio. He describes, from extensive reading and observation, the various forms of excessive, odorous, colored, bloody, urinous, phosphorescent and deficient sweat. Many very curious facts are collected and presented.

——The Annual Report of the Western Pennsylvania Hospital for the Insane has a number of statistical tables and an able report by Dr. J. A. Reed. He believes that insanity is and must be on the increase in modern life, and discusses the cause of this sad fact. He adds the interesting observation, that it is more strongly hereditary in the higher classes of society (p. 9).

——The 10th Annual Report of the Philadelphia Dispensary for Skin Diseases shows a total of 436 patients treated. The physician, Dr. H. W. Stelwagon, says:—

The diseases met with were, as a rule, of a decidedly chronic nature, and, in many instances, had been aggravated by the treatment of ignorant charlatans or by the use of one or several of the cure-all salves.

——The second of Morton's Pocket Series includes "Aphorisms in Fracture," by Dr. R. O. Cowling, of Louisville. The author has added the criticisms of three or four eminent surgeons, and as it now stands his work is a very complete and valuable one, embracing in brief the most definite and certain results of modern surgery. Published by John P. Morton & Co., Louisville. Price 25 cents.

——A strong plea for better nursing and home treatment of the insane is offered in a pamphlet entitled, "The First Requisites in Physician and Nurse, for the Cure of Insanity," by H. O. Ward, of this city. The author insists that higher wages should be paid nurses, in order to secure better ones; "a lady should be the nurse of a lady;" non-restraint is advocated. The writer seems to have had but little actual experience in the treatment of the insane.

——In a reprint from the Illinois State Medical Society Transactions, Dr. J. G. Hervey, of Grove City, describes a case of herniotomy, and one of extirpation of the parotid. Of the latter he observes:

Extirpation of the parotid gland was first performed in this country by Dr. Warren, of Boston, in 1798, and was afterwards generalized by Dr. George McClellan, of Philadelphia, who operated in eleven cases, of which ten recovered. This operation, although laid down by Gross and others as one of the most formidable in surgery, is in a large majority of cases rendered comparatively easy by the anatomical changes caused by inflammation, especially in cases of long standing.

——In a reprint sent us, Dr. T. S. Dabney, of New Orleans, reports sixteen cases of dropsy and Bright's disease, treated with tincture of apocynum, made from the fresh root, ℥j to ℥vj of alcohol, the dose gtt. v–xxx. In some cases this acted as a powerful aphrodisiac. The results were very good. He closes with these words:—

I have not pretended to state that the apocynum exercises any specific action in Bright's disease, but it is worthy of notice that in almost every instance where it was administered in that affection marked diminution of albumen and casts occurred; and in some instances every trace of both disappeared. Whether or not this remedy exerts any peculiar influence over Bright's disease, clinical facts do not allow us to state positively. The following advantages, however, possessed by the apocynum should commend it to all physicians:—

1. The small quantity necessary to produce free diuresis, emesis or catharsis.
2. Its pleasant, aromatic taste.
3. Its fine tonic properties, which compensate for the depression consequent on free catharsis.
4. Its harmlessness—an over-dose being speedily followed by free emesis.

With this remedy at our command, I conscientiously believe paracentesis to be in most cases unnecessary.

OUR EXCHANGES.

Harper's Monthly, Weekly, and Young Folks, come promptly, and are full of very readable matter. The contents of the March number of the *Monthly* are very attractive. Moncure Con way's "Bedford Park" is beautifully illustrated, and the University of Leyden, with its valuable portraits, excellent. The pen and pencil pictures of Albany and its Dutch settlement, and of the "Nation in a Nutshell," are pleasant reading. The novel of "Anne" increases in interest with each number. The illustrations of the last three numbers are especially fine. "Harper's Young People," is just the thing to please the children, and is finely illustrated.

Scribner's Monthly, for March, is very attractive and finely illustrated. Mrs. Hodgson's fascinating story of "A Fair Barbarian," is continued, with very interesting papers on "Copley, the Artist" and "Charles and Mary Lamb," accompanied by portraits of each, and several reproductions of the works of the great artist. Several other excellent papers make up an exceptionally attractive number.

St. Nicholas, for March, is very good. Illustrations excellent, and an unusually interesting table of contents.

Littell's Living Age is presenting an exceedingly interesting series of papers, with the third number of "Don John," by Jean Ingelow, and the tenth number of "Visited on the Children," from the Cornhill Magazine.

The American Agriculturist is a monthly of great value, especially to the amateur farmer and gardener.

Our exchanges of weekly and religious family newspapers are regular and excellent.

BOOK NOTICES.

The Human Body; an Account of its Structure and Activities, and the Conditions of its Healthy Working. By H. Newell Martin, D. Sc., M.A., M.B., Professor of Biology in Johns Hopkins University, etc. New York: Henry Holt & Co. Cloth, 8vo, pp. 621. Price $2.75.

This is one of the American Science Series, for high schools and colleges, which Messrs. Holt & Co. are publishing. It is, as its title denotes, a popular exposition of anatomy and physiology, as those sciences now are. Beginning with the general structure and fundamental physiological actions of the organism, the author passes to the blood, the bony and cartilaginous skeleton, the muscular tissues, and the motor functions, the nervous system, the heart, blood vessels and circulation, the secretory tissues and organs, the food and its transformations, the respiratory mechanism, nutrition, bodily heat, sensation and the special senses, adding an appendix, separately paged and indexed, on reproduction and development. This scheme is a philosophical one, well suited to the natural relations of the subject matter.

The style of the writer is clear and correct, and his presentation of his subject well calculated to interest in it the inquiring mind of the young. It is, perhaps, rather too extended and minute for a text book in ordinary classes, but to accompany lectures on these subjects it is very well adapted indeed. For the general reader who desires information, no better guide could be named.

The application of the facts given to hygiene is made frequently, and the advice is sound and free from hobbyism and platitudes.

Special praise should be awarded the publisher for the neat manner in which the volume is published. It has about one hundred and seventy illustrations, well cut, and some printed in colors; the print is of a size readily legible, and paper and binding will satisfy the most exacting; it forms a pleasing contrast to any of the older school books on anatomy and physiology, in all these respects.

Bodines; or Camping on the Lycoming. A Complete Practical Guide to Camping Out. By Thad. S. Up de Graff, M.D. Philadelphia: J. B. Lippincott & Co. Cloth. 8vo.

This work is the record of the actual experience of two ardent anglers, who, for a number of years, have spent the month of June camping out upon the banks of the Lycoming Creek, Pa., and enjoying the charming scenery which surrounds it. It is intended to bring the merits of this part of our country to the notice of the disciples of Isaak Walton, and also to give a number of practical hints how to prepare for camping out, and how to enjoy the time when in the woods. It is pleasantly written and neatly illustrated, and there is a good deal of solid instruction to the adventurous angler scattered through its pages. As the author is a physician, he very appropriately looks at his subject from the point of view of its healthfulness as well as its pleasurable features. In very many cases no better remedy for the exhaustion incident to the strong competition of modern life can be suggested than a month or two spent in the primeval forests.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE. — COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS. — MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS. —SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3 20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents.

Full catalogue on application.

THE AFTER EDUCATION OF GRADUATES.

During the last few weeks a thousand or two new physicians have been added to the cohorts which already possess the land. They have entered the ranks of a profession where there are few vacancies, and in which it is peculiarly difficult to make a career by push and energy. It is a discouraging feature of this profession, that it hems and impedes the vigorous ambitions of youth, not only by the peculiarities of its self-made laws, but also by the strong opinion of the public, that mature years and long experience are essential to a complete physician.

How well provided are the majority of these young physicians, these neophytes of the profession, in the means of getting along? The question is a serious one for each of them. These requisites are in the first instance, a sound professional education, next, correct personal habits, thirdly, a sufficiency of resources to tide over the inevitably small income of the first few years.

That the education obtainable from the two years or even three years' course at our medical colleges is deficient, is acknowledged on all hands, That many a one is forced by circumstances to rest content with it, is true—too true; but those who have means or opportunity to extend it by a year in a hospital, or by engaging in a clinic or dispensary, should by all means do so. In no other way could the time be spent to more practical profit.

There are also certain branches of great advantage to the physician, in fact, quite indispensable to him if he intends to become profound in his knowledge, which he must study after graduation. One of the most prominent of these is *biology*, the doctrine of *life* in its broad sense. This is now pursued through botany and zoölogy, the sciences which are concerned especially with organic forms. It is not too much to say that almost any question in physiology or pathology analyzed to its elements, leads to the recondite laws of biology; investigations into the nature of epidemics, into the action of remedies, into the forms and functions of tissues, all lead up to the study of biology.

Intimately associated with this, as well as with clinical researches, is the art of *microscopy*. No one nowadays can expect to arrive at any distinction in medicine, unless he is well skilled in the use of that marvelous instrument, the microscope. The most wondrous operations of nature are hidden from men's eyes; they are performed in the dark, and concealed in the infinitely little. This instrument enables us to pry into these arcana, and discover the elemental forces at work in their simple forms.

It is unfortunate that for the study of these branches we are so little prepared, so inadequately equipped, in most of the medical schools of this country. This want was forcibly set forth in the opening lecture, by Dr. J. T. ROTHROCK, of the Auxiliary Faculty of the Medical Department, University of Pennsylvania, last week. In pointed terms he signalized the deficiencies for the higher education of physicians in the United States as a fact not creditable to our country and not in keeping with the wealth we possess and the liberal expenditures we make in many directions.

"So far," he said, "as any land fails to provide for the mental culture of the most aspiring student, it fails in its duty to civilization, and the students will seek that culture elsewhere. I am sorry to be compelled to state that America has fifteen hundred of such students abroad to-day, for whom no adequate provision has been made at home. No such exodus comes from Europe to our schools, because Europe offers greater facilities for study."

"The needed facilities are not necessarily expensive. Simple instruments, costing not more than $5000 or $6000, do all the work at Strasburg, Wurzburg, and other German schools. We need such laboratories here, and till we have them we cannot equal Europe, and every student who leaves these shores shows what we still lack of the true standard. The study of disease germs is very important, and is growing in importance and usefulness. No physican can know too much about it. To take an advanced stand he must be able to check the spread of disease. He must know enough of geology to comprehend the subject of the soils in drainage, and medical jurisprudence and toxicology are of the first importance; for how often he is called upon to give his opinion as an expert. Let him prepare himself to go into court with confidence, and do this even while knowing that life or death depends upon his evidence."

In Europe, he said, there is no such thing as classes, as they are understood in this country. The whole course lasts four years; a student, after the first examination, being allowed to practice, usually in the hospitals, and receiving his degree of M. D. only after an exhaustive examination and the production of a strictly original thesis. He cautioned the class against being, as a German professor pronounced his students, "so fearfully learned that they could not see what was right under their eyes." He insisted on the importance of the four years' course, and suggested that scholarships might be established by the alumni and undergraduates themselves.

Such suggestions as these are appropriate, and may be applied to all of our medical schools. In none of them are the facilities for such advanced studies as good as they should be. The reason does not lie in the lack of interest in scholars, but in the absence of financial support, and, in a measure, in the unwillingness of able men, who could make more in practicing, to devote their time to rather unremunerative abstract pursuits. In time, this will doubtless be changed. Satisfactory incomes will be granted to those willing to make such recondite investigations the main business of life; and the credit of discoveries and the benefit to be conferred by imparting such knowledge will overweigh the diminished financial success achieved.

There are other directions in which the graduate may extend his education with much profit, and thus fill in the hours he is doomed to spend waiting for his patients. If he is not acquainted with French and German, he may readily acquire either or both. It is no harder, and costs no more money—not so much—to learn German, as to learn to play a fair game of billiards; and so far as we have observed, it is equally pleasurable

and more useful. In many localities it gains patients as well as opens a new source of professional improvement.

Notes and Comments.

Cavazzini's Case of Gastrectomy.

In gastrectomy a part of the stomach, generally at the pylorus, is excised, on account of cancerous deposit. M. Petit, in *La Revue des. Sci. Med.*, Paris, Oct., 1880, cites several experiments of Czerny, where annular or oval portions of the stomach were excised in animals, recovery taking place after the operation; the entire stomach was removed in a dog, which lost flesh at first but subsequently (nine months later) had regained its flesh.

The operation has proven very fatal in the human subject, and has been performed but a few times. M. Pean performed it for a cancerous tumor confined to the pyloric region of the stomach.

Although the operation was performed with every antiseptic precaution, the patient succumbed four days later, notwithstanding that two transfusions of blood had been made.

Langenbech performed the same operation for cancer; it was found necessary to completely extirpate the pyloric portion of the stomach and unite the organ with the horizontal portion of the duodenum (*Deutsch. Med. Woch.*, May 15th, 1880).

In Cavazzini's case the stomach was opened at first unwittingly. A young woman of twenty-seven seemed to be in excellent health and had given birth to three children; after the birth of the last she commenced to suffer from pain in the epigastrium, which, though intermittent, became finally insupportable, inducing anorexia, vomiting and insomnia.

The pain was seated in one point where there existed a small and very hard tumor, about three and a half to four centimeters in diameter. This was considered to be a fibro-cartilaginous growth developed in the aponeurosis of the rectus muscle. Every means of relief, injections of morphine, atropia, etc., were unsuccessful, and the patient commencing to lose flesh, an operation for the removal of the growth was determined on. An incision was made over the tumor and the skin carefully dissected back; in cutting about the tumor a cavity was suddenly entered which proved to be the stomach; the anterior of the parietes of the organ and the abdomen adhering solidly at this point; the tumor, including a portion of the stomach, was carefully excised and superficial and profound sutures passed. After the sutures were removed there remained a small fistule, which closed on the fifteenth day, compression being made by means of a bag containing 500 grams of bird shot.

But erysipelas occurred later and was followed by an abscess in the abdominal parietes, which retarded complete cure until the end of the second month.

Seven months later the patient commenced to suffer from the same troubles, and there existed induration at the point where the operation had been performed. She again became enceinte, and scrofulous tumors appearing in the neck, condurango was administered, and the pain disappeared, together with the induration in the epigastrium.

Labor took place at term, the child dying later, of scrofula. In 1878, that is four years later, the patient again became enceinte, but she was at the time suffering from tubercular lesions in the lungs, gave birth to a dead child in the eighth month, and succumbed herself shortly afterwards.

At the autopsy large vomicæ were found in the lungs; the stomach was displaced towards the left and adherent to the spleen. There was a stricture of the stomach between the less and greater curvature, corresponding to the cicatrix left after the operation.

Gastrotomy for Removal of Foreign Bodies.

In the *Revue Generale*, by M. Petit, in *La Revue des Sciences Medicales* (Paris, Oct., 1880), he rather deprecates M. Labbé's method of operating. M. Labbé makes a transverse incision over the stomach, opens the peritoneum on a grooved director, and then drawing the stomach outward, sutures it to each lip of the wound. Then the organ is opened between the sutures, the foreign body extracted, and the stomach allowed to remain in this position; consequently, after cicatrization it remains permanently fixed to the anterior parietes of the abdomen. M. Petit considers that this might interfere with the digestive functions, and in a case reported by Cavazzini, pains attributable to these adherences were noted; again cicatrization is often obtained with difficulty, permanent gastric fistula occurring in some cases, and proving very difficult of cicatrization.

M. Petit advises the temporary fixation of the organ by acupuncture needles passed at the angles of the wound; the incision is then made, and the foreign body extracted. Sutures of carbolized catgut are then passed in the gastric incision, and the organ returned within the abdo-

men. Colin remarks (*Thèse de Paris*, 1877), that but three deaths occurred in 15 cases of gastrotomy for extraction of foreign bodies; while two deaths occurred in 32 cases where no operation was performed.

Inhalations of Turpentine Vapors in Pertussis.

M. Barety, of Nice, reports, in *l' Union Médicale*, that he had at one time four patients in the same family under the usual modes of treatment in pertussis; emetics, belladonna, etc., were tried with little success. At the height of the spasmodic period one of the children was placed in a newly painted room where the odor of spirits of turpentine was very evident; from that moment the fits of coughing became less intense and less fatiguing, and the malady did not have as lengthy a duration as in the other children. M. Barety considered that the amelioration was due to the inhalation of the vapors from the spirits of turpentine, and since that time he places deep plates containing this liquid under the head of the bed, and in the corner of the room in which the little patient sleeps; in this way the turpentine vapors fill the room, which should, however, be freely ventilated twice daily.

The paroxysms of coughing soon become less marked, and the malady takes on a benign character, and lasts generally about one month.

Treatment of Scabies.

M. Fournier, in his lectures on the treatment of scabies, gives the following prescription for an ointment, to be preferred to that of Helmerich, which often proves too irritating:—

℞.	Sodæ carbonat,	℥ iss	
	Sulphur. sublim.,	℥ iij	
	Tragacanth. gum.,	gr xv	
	Glycerinæ,	℥ vj.	M.

The preliminary friction with black soap (St. Louis Hospital mode) may be replaced by prolonged frictions with the ordinary toilet soap; the ointment should then be very freely applied over the whole surface of the body, well rubbed in and allowed to remain, the patient putting on his ordinary under clothing, so that any animalcules contained therein may be destroyed at the same time.

Inoculating Kine.

Dr. S. E. Wills, of Maryland, writes us:—

"I notice Dr. Dingee's article in February 26th, 1880, No. of Reporter. If he desires to try the experiment of producing vaccinia from variolous matter inoculated in the cow, I hope his experience will be more satisfactory than some I made about twenty years ago, an account of which was published in the Reporter at the time. I had about forty or fifty cases of inoculated smallpox to deal with, besides a number of cases of variola contracted from inoculated subjects. By some observers the vaccinia transmitted through successive vaccinations, from the time of Jenner is thought to be quite as efficient as the cowpox matter. On theoretical grounds, others prefer the matter direct from the cow. In Maryland, the physicians are furnished gratuitously with bovine virus, and we are prohibited from using any crusts more than two removes from the cow. I have never known a patient who has been three times successfully vaccinated to have varioloid."

Fatal Case of Poisoning by Chlorate of Potash.

In the *Marseille Médical* is the report of a case where a man, sixty-seven years of age, took somewhat over an ounce of chlorate of potash dissolved in warm water, delivered through mistake for epsom salts. Death occurred in seven and one half hours, and was preceded by the following symptoms: vomiting of greenish matter, colic and diarrhœa; general collapse, rigidity of the lower limbs and asphyxia. After death the skin of the back had a slate-colored tinge.

It is well known that the potash salts are poisons which act on the muscles and particularly on the heart. Sulphate of potash is ten times more poisonous than the corresponding soda salt, and chloride of potash may prove poisonous, while the chloride of sodium or ordinary table salt is inoffensive.

Special Reports.

VII—MEDICAL ELECTRICITY.

Mode of Action of Electricity.

Usually electricity is spoken of as a stimulating agent. But in the *Medical Record*, November 20th, 1880, Dr. T. W. Poole, of Canada, insists that in all degrees of strength the current is a paralyzer. He will not acknowledge that it is a stimulant, tonic, or vitalizer. At least not directly so; and he undertakes—not with much success, we think—to argue on the subject, *a priori*, in the following wise:—

Electricity is one of the forces of nature, and the mode of action of the natural forces is necessarily invariably uniform and consistent. From the spark of the battery to the flash of lightning there is an immense progression in power, but the addition of any number of sparks to that of the battery can in no way change its character or modify its mode of action, which is ever the

same, and tends toward the same goal. Just as the flash of lightning kills, the battery spark tends to kill, in proportion to its power, and only fails to kill because of its feebleness and the counteraction of opposing forces. We take advantage of its weakness (as we do of fire, water, heat, etc.) to render it beneficial to us; and if the *effect* produced is different from that of the very powerful current, or the scathing lightning, it is not that the thing itself has changed its nature or modified its mode of action. If the greater discharge of electricity is a paralyzer, the battery spark is a paralyzer too, in proportion to its power; the difference being not in quality, but in degree. To assert otherwise is to controvert the plain teaching of natural science.

The error which lurks here is in the conception of nerve force. This is not a simple but a complex resultant force, holding its nature and existence from the combination of the elementary forces; each is a stimulant to it in certain degrees; each paralyzing and destructive beyond this degree.

Applications of the Faradic and Galvanic Currents.

Some sound and practical suggestions are given by Dr. A. Gunther, of Zurich, in the *Centralblatt für Chir. Med.*, No. 30, 1880. He teaches that the faradic current has valuable applications in the following diseases: 1. *Asphyxia*, both of infants and in that which occurs in catarrhal pneumonia, convulsive cough, atelectasis and accidents. One pole with a broad electrode is to be placed in the interscapular space, while the other, in the shape of an electric pencil, is to be run up and down the thorax and abdomen, after thoroughly drying the skin. 2. *Pendulous abdomen.* One electrode at the sternal insertion of the rectus abdominis, while the other is run up and down the muscle, the stream to be strong enough to induce forcible contraction of the biceps. 3. *Habitual constipation.* One electrode with a broad base on the perineum, while the other is carried up and down the course of the colon. 4. *Chronic cystitis*, with thickening of the vesical walls and incontinence. Electricity is contraindicated where erosions or ulcers of the vesical mucous membrane are present. One pole may be placed on the perineum, the other over the symphysis; or the one over the symphysis, and the other inserted as a catheter into the bladder. 5. *Impotence.* The testes can be taken between the two electrodes; or the glans can be placed between them.

The galvanic current is particularly efficacious in 1. *Chronic pleuritic effusion.* The anode on the sternum, the cathode *in loco dolenti;* a battery of 18 Stöhrer elements. 2. *Chronic periostitis:* The negative pole at the seat of disease. 3. *Chronic muscular rheumatism.* Use 8 to 10 elements, broad electrodes, moved slowly up and down each muscle for about two minutes at a time.

Dried Collodion as an Electrical Agent.

Dr. Seure, of Paris, has published a memoir, which was presented, last summer, to the Academy of Medicine, on the electric properties of dried collodion. He finds that thin leaves of this substance, which may be detached from glass or metal plates, are negatively electric in the very highest degree, sulphide of copper and gutta-percha being positive in respect to them. In the dark they become luminous by friction, and when rubbed with the fingers they give rise to a sensation of numbness. If the outside of a bottle be covered with collodion, and then rubbed, small sparks can easily be obtained. Dr. Seure thinks that some therapeutic effects may be obtained from this substance. He suggests that leaves of dried collodion should be sewn on the inside of the garments worn by hemianæsthetic subjects, or that they should wear under sleeves or leggins of collodionized silk.

Disturbances of Menstruation.

In the *Allg. Med. Cent. Zeitung*, Nov. 10, 1880, Karl Kihn states that he has had recent opportunities to convince himself of the value of the electrical current in amenorrhea and dysmenorrhea. He especially advises it in connection with hot infusions of juniperaceæ and warm foot baths. His plan is to place one electrode in the hand of the patient and to lay the other in the water of the foot bath. In a number of cases this simple measure increased the flow, relieved the pain, and established a regular and comparatively comfortable return of the periods.

The Induced Current as a Stimulant in Parturition.

A valuable study of the effects of the induced current in parturition, based on the observations of 41 cases, is contributed to the *Lancet*, Jan. 1, 1881, by Dr. W. J. Kilner, electrician to St. Thomas' Hospital. He uses it especially in cases where the pains are short, feeble and at long intervals, and states:—

My first experiments were especially directed to discover whether the pregnant uterus, like the voluntary muscles, possesses *motor points.* After many trials, the conclusion I arrived at is that motor points exist, and can be easily found bisecting the line drawn from the umbilicus to the middle of Poupart's ligament. This point is approximate, being only applicable before the uterus has descended, to allow the head of the child to enter the pelvis, and the spot varies slightly in each case according to the position of the uterus. When we talk of motor points, we must recollect that the uterine muscular fibres

are of the unstriped variety, and that they do not respond to galvanic stimulation so quickly as the striped muscles.

When the poles of the coil are placed upon the spot just indicated, the first thing observed is the immediate contraction of the abdominal muscles, the intensity of which depends upon the strength of the current. Occasionally, at the instant of contact, uterine contractions commence, but more often a lapse of about a quarter of a minute is required, and not unfrequently they are delayed for two or three minutes. But still the current is taking effect, as the intermittent use, for instance, half a minute on and the same off, rarely fails to induce contractions in a few minutes; these increasing gradually in severity and duration, while the intermissions become less and less. Latterly, however, I have applied the current only during the contraction, to obtain the benefit of the relief of pain.

He appends the details of several cases, one of which illustrates a frequent occurrence—namely, that *the pains do not cease until the current be discontinued*, but however more frequently, although the pains become very prolonged, yet they stop of their own accord. It it be wished merely to prolong any one uterine contraction, the current is best applied near the termination of the pain, when it will commence *de novo*.

From the observations he made he found it comparatively easy to say beforehand what patients are the most likely ones to be affected favorably by the induced current, viz: (1) Those of a nervous temperament, who are easily excited, and who usually feel pain acutely; (2) those who have sympathetic disturbances, such as vomiting and hiccough; (3) those who require stimulation. In Dr. Kilner's opinion, the best way of applying the current is to place the electrodes (each being about three inches in diameter) upon the abdomen, over the motor points, these being retained in their proper places by the binder. It is easy to make flat electrodes of spongio piline by running through the waterproof covering several wires, in different directions. Large electrodes are preferable to small ones, because the same current spread over a large surface is not felt so acutely as when it is concentrated into a small space. For the relief of pain a very mild current is only required, but for the production of uterine contractions a variable strength is necessary.

Galvanization of the Medulla in Diabetes Insipidus.

The researches of Claude Bernard established the fact that pricking certain points on the floor of the fourth ventricle causes polyuria, sometimes with, sometimes without sugar. As this and other experiments seem to indicate that the seat of the affection is in the medulla, it occurred to Dr. Julius Althaus, to apply this clinically and to resort to galvanization in a case of diabetes insipidus, which he reports in the London *Medical Times and Gazette*, November 27th, 1880:—

A gentleman, aged thirty-seven, single, consulted me on July 27th, 1880. He had spent many years in the tropics, and had suffered from persistent diarrhœa, which nothing would arrest. This ultimately brought on a state of complete cerebral exhaustion, and he was entirely incapacitated from attending to his occupation. The most troublesome among the numerous symptoms from which he suffered, however, was that of polyuria, which was so bad as to exclude him altogether from society. When in company, he could hardly sit still for a quarter of an hour without experiencing a most pressing desire to empty his bladder; and this annoyance had led him to adopt a solitary mode of life. The average quantity of urine which he passed during the day amounted to ninety ounces, but often much more. It was feebly acid, had a low specific gravity, and contained no sugar or albumen, nor any excess of urea. As he had taken gallons of physic without the slightest relief, he wished to ascertain from me whether any mode of applying galvanism to him might be expected to be of service; and I therefore proposed to apply the constant voltaic current to the medulla. He eagerly grasped at this proposal, and I then applied the current of fifteen cells of Becker-Muirhead's battery to the occiput, taking care that the medulla received alternately the influence of the anode and cathode, and regulating the finer degrees of voltaic power by means of the rheostat. The application lasted altogether six minutes, and was entirely painless.

The patient came to see me again a week afterwards, and informed me that the result had been completely successful. The quantity of urine passed during the day had, after the application, fallen to thirty ounces; and while formerly he had often had incessant calls to pass his water, he had since then only been obliged to pass it three times a day. This improvement was also permanent.

The Electro-Magnet in Paralysis of Sensation.

An interesting application of the electro-magnet was reported last summer, in the *British Med. Jour.* (August 7). Three cases of partial paralysis with anæsthesia are related by Dr. Dreschfeld. They were as follows: 1. Hysterical anæsthesia affecting both sides of the body, and also the special sense organs. 2. Partial epilepsy, most probably of syphilitic nature; anæsthesia. 3. Left hemiparesis, with involuntary movements of arm and leg; left hemianæsthesia; left hemianopsia; mental disturbances.

The immediate effect of the electro-magnet in all the three cases is reported as very striking. In the first case, the application was so conducted that there could be no deception on the part of the patient; the second case closely re-

sembles cases of meningeal syphilitic inflammation; in the third case there can be no doubt as to the presence of organic lesion. The anæsthesia in the second case might have been cured by the prolonged administration of iodide of potassium; and in the third case it might have gradually diminished, but the sudden effect produced by the magnet is specially interesting from a physiological point of view.

Negative results were obtained from the use of the magnet in two cases of progressive muscular atrophy, accompanied by analgesia without anæsthesia, also in lesions of peripheric sensory nerves. It seems, therefore, that the magnet is only of use in cerebral cases, and would thus be of diagnostic value in doubtful cases.

The Galvano-Cautery in Nasal Catarrh.

This plan of treatment has been tried by Dr. W. C. Pipino, of St. Louis (St. Louis *Medical and Surgical Journal*, 1881). He states that cases where most benefit is derived from the application of the galvano-cautery are those in which there is great structural change, as hypertrophy of the mucous membrane over the inferior and middle turbinated bones, causing an obstruction to the free passage of air through the nasal passages; deflection of the septum to the right or left must not be mistaken for hypertrophy of the membrane covering it, although we frequently find the membrane covering the posterior part of the septum hypertrophied, as well as that over the turbinated bones; defective hearing, excessive secretion, with the formation of crusts, and follicular degeneration of the membrane of the posterior nares and pharynx.

Nothing short of the partial or total destruction of the hypertrophied tissues will answer. The cicatricial contraction of the tissues from the heated wires deprives it of its erectile nature, removes the obstruction, allowing the free passage of air through the nose.

Electricity in Asthma.

Dr. R. Schmitz reports (in *Deutsche Med. Wochensch.*, 20th November, 1880) a case of asthma in which the good effects of the induced electric current were manifest—the patient, a man of forty, having obtained no relief from any of the means usually resorted to in such cases. It was noticed that each attack was preceded by a catarrh, which invaded successively the larynx, trachea, and bronchi; on the supposition that the pneumogastric nerve was probably subjected to pressure in its course by the swelling of the respiratory mucous membrane, it was determined to treat the nerve directly by electric currents. At the first *séance*, which took place in the evening, the electrodes were placed on the sides of the thyroid cartilage, at the internal border of the sterno-mastoid muscle. The current, at first feeble, but subsequently gradually increased in intensity, was passed for nine minutes. The relief which followed was so marked, that the patient slept the greater part of that night. Two applications of the current were made daily, for fifteen minutes each time; after the twelfth application the asthma, and with it the bronchitic râles, had disappeared. A subsequent attack was readily cured without electricity. It must, however, be borne in mind, that faradization of the pneumogastric nerve must be set about cautiously, as, if the current employed be sufficiently strong, the heart's action may be definitely arrested.

The Electric Treatment of Exophthalmic Goitre.

On this subject a paper by Dr. A. D. Rockwell, detailing the results of the treatment in nine cases, will be found in the *Trans. Am. Med. Assoc.*, 1880. It appears, in about one-half the cases it is of positive and permanent benefit.

Another valuable paper in this volume is on

The Strong Galvanic Current in Obstinate Sciatica.

The author, Dr. V. P. Gibney, relates thirty-two cases thus treated with very good results. Daily applications are made for at least a fortnight. The electrodes are applied in turn over every point of pain. A constant current of Leclanché battery is used, as strong as the patient can endure. Marked good results show themselves after two or three séances.

In the same volume is an essay on

The Galvano-cautery in Diseases of the Naso-Pharynx.

By Dr. W. H. Daly, of Pittsburgh. In estimating its value in such diseases, he does not place it very high, and doubts if the instrument will become popular, as "its expense is considerable and its behavior capricious." In most tumors and growths the mineral caustics are preferable, as they are both cheaper and "altogether less liable to be followed by serious local or constitutional symptoms."

—Louis Lessard, of Montreal, was born in Paris, France, in 1777, and on March 7th he fulfilled the duties of a Coroner's juror with the keenness of intellect of a man half his age. He owned a silver snuff-box, presented to him by Napoleon I, after the battle of Austerlitz. He served under Napoleon in most of his great battles, ending at Waterloo. He removed to Canada in 1830.

Correspondence.

A New Test for Glycosuria.

Ed. Med. and Surg. Reporter:—

Having a vial containing some suspected urine in my hand, standing beside a hot stove, the thought occurred to me, that if there is sugar in it, by dropping a small quantity of it upon the stove I will get the smell of burnt sugar. The thought prompted the act, when "presto," the room was filled with the characteristic fumes. I then proved it by the yeast test, and a neighbor, by the copper and urinometer.

I have no recollection of hearing or reading of this test, but I believe it will prove infallible.

Carlton, New York. T. R. Bamber, m.d.

Quintuple Birth.

Ed. Med. and Surg. Reporter:—

September 18th, 1880, at two o'clock, I was called to see Mrs. H., of this city, who was about to be confined, for the fifth time. Found her in poor health, pale, had a weak pulse and her feet and ankles were considerably swollen. She is thirty five years of age, and has never had more than one child at a time before. At this time the pains were light, as they were during the whole time of the labor, she not having sufficient strength to assist at any time the expulsive force of the uterus.

On examination per vaginam, I found a breech presentation, and the hips entering the superior strait. The labor proceeded slowly and naturally until a little after four p. m., when the first child was born, without making any perceptible difference in the size of the mother.

After cutting the cord I made an examination, and found the feet of a second child presenting. This one was born about nine o'clock, p.m., without any trouble, except that the labor was tedious, on account of weakness of the woman.

About this time I began to comprehend the situation, for after the birth of two, there did not seem to be much decrease in the size of the abdomen. The cord being cut, on examination I found the feet of a third one presenting. This one was born at 2 o'clock, a. m., of the 19th, a fine, plump boy, but still-born. After cutting the cord, I found still another one, with the feet presenting.

You ought to have seen the expression on the faces of the women present, as they looked at one another! I cannot describe it.

This (fourth) one was born in about half an hour, and still-born. Now I thought that must be all, and after waiting awhile proceeded to remove the placenta, or placentæ. After removing one, my finger came against something sharp, which surprised me at first, but I soon found it to be the ends of the fingers of a fifth child, whose head was now in the hollow of the sacrum with one hand over the head. The pains had all ceased. After waiting a considerable time, and doing all I could to bring on the pains again, without success, I sent for the forceps. They having arrived, I delivered her in a few minutes without trouble. This one was also still-born. The lady made a good recovery in about the usual time.

The first child lived two weeks, the second one three days. The others, as stated above, were still-born. They were all well-developed and came at full term. The weight of the five was nineteen pounds. First one five pounds, second one four pounds, and the others a little over three pounds apiece. There were two placentæ, three cords attached to one and two to the other.

Monticello, Ill. James Moffitt, m.d.

News and Miscellany.

College Commencements.

Jefferson Medical College.

The fifty-sixth annual commencement of the Jefferson Medical College was held at noon on Saturday, March 12, in the Academy of Music. The building was filled to its utmost capacity. On the stage were seated the Trustees and Faculty of the College and invited guests. The graduates, numbering two hundred and five in all, occupied seats in the main part of the orchestra. After prayer had been offered by Rev. I. L. Nicholson, of St. Mark's P. E. Church, Dr. E. B. Gardette, President of the institution, conferred the degrees upon the graduates.

The following prizes were then announced and awarded:—

1. A prize of $100, by Henry C. Lea's Son & Co., for the best thesis, to Henry D. Bruns, of Louisiana, with honorable mention of theses of C. W. DeLarmoy, of Pennsylvania; Robert Lee Payne, Jr., of North Carolina; and H. J. Williams, of Georgia.

2. Prize of $50, for the best essay on a subject pertaining to surgery, to Joshua Ellegood, of Delaware, with honorable mention of the thesis of M. J. Cohen, of Penna.

3. Prize of $50, for the best essay on a subject pertaining to obstetrics, to S. Howard Wilson, of Pennsylvania, with honorable mention of J. H. Koons and E. R. Smiley, both of this State.

4. Prize of $50, for the best essay on a subject pertaining to Materia Medica and Therapeutics, to J. C. Martin, of Ohio, with honorable mention of L. M. Bullock, of New Jersey, and S. S. Ullrick, of Pennsylvania.

5. Prize of $50, for the best anatomical preparation, to E. N. Taylor, of Pennsylvania.

6. Honorable mention, by Professor Rogers, for the best original research in the chemical laboratory, to L. L. Artis, of Cuba.

7. Prize of a gold medal, by Professor Chapman, for the best final examination in physiology, to A. J. Dodds, of Syria.

8. Prize of a gold medal, by R. J. Levis, m.d., for the best report of his surgical clinics at the Pennsylvania Hospital, to G. W. Stout, of Pennsylvania, with honorable mention of the report of Charles F. Spangler, also of this State.

9. Prize of a gold medal, by Thomas G. Morton, m.d., for the best report of his surgical clinics at the hospital, to L. L. Rogers, of this State.

The Valedictory address to the graduates was

delivered by Prof. Roberts Bartholow, M.D., after which the exercises were concluded with the benediction.

Dental Colleges.

The two dental colleges in this city turned out one hundred and twenty-five graduates on February 26th. At noon the twenty-fifth annual commencement of the Pennsylvania College of Dental Surgery was held at the Academy of Music, a large audience being in attendance to witness the ceremonies.

The following gentlemen were awarded prizes: William Lewis Cave, James G. Palmer, L. Bischoff, Eduardo Gaviria, W. Dammann, G. L. Simpson, A. M. Lorens, L. P. Cook, R. F. Guenther, E. Dalman, Oscar Klien and G. V. I. Brown.

In the evening the eighteenth annual commencement of the Philadelphia Dental College was held at the Academy of Music. There was a large audience present and the floral tributes were numerous.

Other Colleges.

On February 24th the Fort Wayne Medical College graduated twenty-two M. D.s. Dr. Van Sweringen delivered the address to the graduating class.

On February 25th, the Louisville Medical College graduated a class of fifty-four. The valedictory address was delivered by Dr. A. H. Keller, of Kentucky.

The Ohio Medical College, in Cincinnati, turned out one hundred and three graduates on Wednesday, March 2d. The Pulte Medical College (Homœopathic), forty. The College of Medicine and Surgery, thirty; and the Ohio Dental College, twenty-nine.

The Little Rock Medical College, March 2d, graduated ten students.

The Jefferson Alumni Association.

The Alumni Association of Jefferson Medical College held their annual meeting Friday, March 11, in the lecture room of the college, Professor S. D. Gross, the President, in the chair. Considerable interest was awakened by a resolution offered by Dr. S. W. Gross, requesting the faculty to prohibit any student from competing for a prize unless he has taken three courses of lectures. The resolution was withdrawn after some discussion, Dr. Gross saying that he only desired to call the attention of the faculty to the subject. The usual reports of committees were presented, and the present officers were re-elected for the ensuing year. In the evening, after an oration by Dr. Osgood, the annual alumni supper was given at Augustine's. Professor Gross presided, having on his right the orator, Dr. Osgood, and on his left Professor Beverly Cole, of the University of California, and among the thirty or forty others at the table were Professor R. E. Rogers, Dr. Hewson, Dr. Pancoast, Dr. J. H. Brinton, Dr. Andrews, Dr. Keen, Dr. S. W. Gross and other prominent practitioners. Toward the end of the banquet a few formal toasts were given, Dr. Osgood replying briefly to that to "The Orator;" Dr. Cole responding on behalf of "Our Guests;" Dr. Hewson for "The Alumni;" Dr. Rogers for "The Jefferson Medical College;" Dr. R. J. Dunglison for "The Medical Press," and Dr. Lambdin for "The Daily Press." After all the speeches the health of the Emeritus Professor of Surgery, Dr. Joseph Pancoast, was drunk standing, and the president declared the evening ended.

Women's National Hospital.

The Women's National Hospital at Hartford, Connecticut, designed for the treatment of women addicted to the excessive use of alcohol or narcotics, was recently chartered by the Connecticut Legislature. The Board of Corporators have recently elected the following officers: President, Dr. Marion Sims, of New York; Vice Presidents, Dr. Frank H. Hamilton, of New York, and Dr. George B. Hawley, of Hartford; Secretary, T. D. Crothers, of Hartford. The Trustees are leading physicians from ten different States. The hospital will probably be erected in Fairfield County, Conn.

Longevity of Women.

The recent European statistical returns of the population of Europe have supplied the statistical department at Vienna with the means of making an interesting study as regards longevity. It results from this, that of 102,831 individuals who had exceeded the age of ninety years, 60,303 were women, and 42,528 men. The greater longevity of women is exhibited also by the greater chances of women of attaining or exceeding the hundredth year. Thus, in Italy there are found 241 female centenarians for 141 male centenarians, and in Austria 229 women for 183 men. In Austria there are 1,508,359 sexagenarians, or 7.5 per cent. of the total population.

Items.

—A large number of petitions have been received in the Michigan Senate, in favor of a chair of eclectic medicine at Michigan University.

—Another doctor is presently to be knighted in England. He is Dr. James R. Bennett, F. R. S., President of the Royal College of Physicians.

—Two allopathic physicians, one homœopathic, and one eclectic are serving amicably together, as a committee appointed by the Connecticut Legislature, to draft a Medical Practice act.

—An immense laboratory for chemical analysis is, by order of the Préfet de Police, about to be opened. Experts will there be at the service of the public, for the purpose of analyzing wine, milk, chocolate, coffee, meat—in a word, all articles of consumption—and that for very small fees. This war against adulteration well deserves approval and encouragement.—*Gaz. Méd.*, January 23.

OBITUARY NOTICES.

DR. GEORGE A. OTIS.

We have received the following announcement from the Surgeon General's Office:—

It is with profound regret and a sense of loss,

not only to his corps, but to the medical profession, that the death of George Alexander Otis, Surgeon and Brevet Lieutenant Colonel, U. S. Army, is announced to the Medical Corps of the Army.

Born at Boston, Massachusetts, November 12th, 1830, he graduated with the degrees of A.B. and A.M. from Princeton College; entered the Medical Department of the University of Pennsylvania, and received his degree of M.D. from that Institution in 1850; visited Europe, and prosecuted his studies in London and Paris, and returning to this country he established himself at Springfield, Massachusetts; appointed Surgeon 27th Massachusetts Volunteers, September, 1861, he held this position until appointed Surgeon U. S. Volunteers, August 30th, 1864. After the close of the war he entered the Medical Corps, U. S. Army, as Assistant Surgeon, February 28th, 1866; became Captain and Assistant Surgeon, July 28th, 1866; Major and Surgeon, March 17th, 1880, having received the four brevets of Lieutenant Colonel of Volunteers, Captain, Major and Lieutenant Colonel, U. S. Army, for meritorious services during the war. While Surgeon of the 27th Massachusetts Volunteers, he served in Virginia, North and South Carolina, and was on special duty in charge of the hospital steamer "Cosmopolitan," in the Department of the South. Assigned to duty in this office July 22d, 1864, he was Curator of the Army Medical Museum, and in charge of the Division of Surgical Records until his death.

He was editor of the Richmond *Medical Journal* for three years, member of the leading medical societies of America, and corresponding member of various similar societies in Europe, and a contributor to prominent medical journals. Surgeon Otis, with his personal observations of the surgical collections abroad, brought indefatigable industry and untiring energy to the development of the surgical and anatomical collections of the Army Medical Museum, which he has made the most valuable of their kind in the world. The compilation of the Surgical Volumes of the Medical and Surgical History of the War has placed Surgeon Otis confessedly among the most prominent contributors to surgical history.

While on duty in this office Surgeon Otis wrote for publication no less than ten reports on subjects connected with military surgery, etc.; among which are his most valuable and exhaustive reports on "Excision of the head of the femur for gunshot injury," and on "Amputation at the hip-joint in military surgery." Of great culture, retentive memory, and with a remarkable facility of expression, he was, as a compiler and writer, conscientious in his analysis, giving his deductions from the facts before him, with modesty, but decision. With such a record it is needless to speak of his zeal, his ambition or his devotion to his profession, and especially to the reputation of the corps of which he was so bright an ornament. While devoting himself to the preparation of the third and last surgical volume (now more than half completed) of the Medical and Surgical History of the War, he died in this city, February 23, 1881. His untimely death will be deeply deplored, not only by the medical corps of the army, but by the whole medical profession at home and abroad.

Jos. K. Barnes, *Surgeon General.*

—Wm. Walker, M.D., for eighteen years a practitioner at Monmouth, Ill., died in that city on Sunday, Feb. 20th, in the 61st year of his age. His disease was typhoid pneumonia, complicated with inflammation of the bowels. A native of Pennsylvania, he graduated at an early age from Bethany College, West Virginia, and in 1853 received from Jefferson Medical College, Philadelphia, the degree of M.D. After a few years' practice at Rock Lick, Marshall Co., Va., he moved to this thriving Western city, where the remainder of his life was passed.

Among the medical fraternity of the Military Tract, no one was more widely known or thoroughly esteemed. And in commercial pursuits he proved no less successful than in his chosen profession. For a number of years he was a director of the First National Bank of Monmouth, and a prominent figure in other local enterprises and industries.

As a tribute of respect to his memory the banking houses of the city closed their doors on the day of his burial.

—Dr. Thomas C. Cox, of Trenton, died in Kalamazoo, Mich., last week. He was a student at the Jefferson Medical College, and upon his graduation joined a Pennsylvania regiment as Assistant Surgeon, serving creditably until the close of the rebellion. After being mustered out he practiced his profession for awhile in Chester County, Pa., but soon drifted into journalism, for which he had a predilection and in which he was chiefly occupied.

—Dr. James Burd Peale, of Holmesburg, died suddenly, in this city, on the 2d inst., of disease of the heart. He was prominent as a surgeon during the war, having been, at one time, Medical Director in the army of the Potomac.

—Dr. Andrew Wood, LL. D., a distinguished Edinburgh physician and literary man, died early in February.

MARRIAGES.

DOUGLAS—FULLER.—At St. Andrew's Church, Pittsburg, Penn, Anna Marie, youngest daughter of the late Capt. Fuller, C. E. I. S., to William Douglas, M.D., of Belfast, Ireland.

PARKS—WILLITS.—On 2d Mo. 23d, 1881, at Friends' Meeting House, Downingtown, Pa., Thomas E. Parks, M.D., and Meribah A. Willits.

DEATHS.

BROWN.—At Staunton, Va., February 10th, Dr. J. Lewis Brown, formerly of Philadelphia.

COMFORT.—On the 9th inst., near Wyoming, Minnesota, Dr. J. W. Comfort, formerly of Philadelphia, aged 79 years.

GREGORY.—At Mount Vernon, N. Y., March 2d, 1881, Joseph S. Gregory, M.D., in the 57th year of his age.

PEALE.—In this city, suddenly, on the morning of the 2d instant, J. Burd Peale, M.D.

RUSS.—On Tuesday, March, 1, at his residence, in Pompton, N. J., John D. Russ, M.D, in the 80th year of his age.

STEVENSON.—At Morristown, N. J., on Wednesday, February 16th, Dr. R. W. Stevenson, in the 77th year of his age.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat. according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O	
Quinidia do	15 "	20	24	2	2	
Cinchonidia do	15 "	C	H	N	O	
Cinchonia do	15 "	20	24	2		
Chinoidine Purified,	30 "					

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

Lecture.

PARALLELISM OF THE ERUPTIVE FEVERS.

Abstract of a Lecture delivered at the Hôpital des Enfants Malades, Paris,

BY M. JULES SIMON.

Translated for the Medical and Surgical Reporter.

The diagnosis of the eruptive fevers is sometimes easy, even at the outset of the disease; in other cases it is impossible, even after the eruption has commenced to appear.

There are certain points of resemblance between them all; all are contagious; smallpox, varioloid and measles can be directly inoculated; scarlet fever is contagious principally through the pellicules of epidermis which become detached towards the tenth or twelfth day of the disease.

Measles.—Measles commences by a chill; there is cephalalgia and vomiting, as in the other fevers, but the temperature does not mount suddenly; it gradually becomes higher, to attain its maximum at the moment the eruption makes its appearance. At the same time there supervene symptoms of bronchitis, pharyngitis, accompanied by a hoarse cough, coryza and redness of the conjunctiva, with hypersecretion of tears.

These prodromata exist three or four days before it is possible to establish a diagnosis.

Variola.—The outset of smallpox is violent and the fever intense from the beginning; the ascending line of temperature is not vacillating, as in measles; in twenty-four hours it is at its maximum.

The chill is very violent; the fever, more intense than in measles, is, nevertheless, less marked than in scarlatina.

The symptoms, instead of pointing towards the respiratory organs, are rather those of cerebro-spinal congestion; intense cephalalgia and rachialgia, sometimes accompanied by a sort of paraplegia.

Sometimes a form of erythema, the variolous rash, appears, preferably in the groins, simulating the rash of scarlatina.

There is often, too, vomiting and convulsions, new sources of error in forming a diagnosis; the prodromata in definitive cases last two or three days.

Scarlatina.—Scarlatina comes on very suddenly; the fever is moderate, or, on the other hand, very intense. This peculiarity explains why certain physicians, judging, undoubtedly, from a limited number of cases, have considered this a benign malady; while for others it is the most fatal of all diseases.

It is thus that Tissot has compared the disease to dogs who bite without barking. In the great majority of cases the fever rapidly becomes very violent, the temperature attaining 105° or 106°; a temperature met with in no other disease with the exception of typhoid fever. But during this period the patient in scarlatina suffers from the throat, and on examination the fauces, the tonsils are seen to be scarlet red; white spots soon commence to appear on the tonsils, while the rest of the pharyngeal mucous membrane appears of a dark red color.

The glands about the throat are simultaneously affected; and finally all the symptoms last but twenty-four to thirty-six hours when the eruption appears.

We will return to the consideration of measles; we hear it every day repeated, that the eruption appears first on the face and neck; but in chil dren it is not in this situation that it must be sought for; in them it appears first behind the ears, or on the back.

The eruption is characterized by small red spots (*taches*), which are often papular, and as the tissues of the young child become easily affected with œdema, if the fever is intense, and the child then seen for the first time, it may easily be mistaken for a case of smallpox.

In such a case it is better to defer for two or three days the expression of a positive opinion.

During this early period the prodromic symptoms of measles, coryza, conjunctivitis, etc., instead of disappearing, become more marked.

In connection with scarlatina, of which the diagnosis is often easy, it must be remembered that cases are met with in which there is very little fever or eruption.

Children may be brought to you in the tenth or twelfth day of the disease; there remains no trace of the scarlet rash; small brownish spots are found, which are the seat of epithelial desquamation; this last sign must be carefully sought for, particularly on the back and in the armpits.

The eruption in smallpox occurs on the face and hands, and on the lower limbs. It consists of papules, which on the third are surmounted by a vesicle, which becomes umbilicated, and the liquid contained therein purulent; dessication occurs about the fifteenth day.

On the eighth day, that is, at the moment of suppuration, the temperature, which had fallen, becomes almost as high as at the beginning of the disease (secondary fever). In varioloid dessication commences after the sixth day, and there is no secondary fever, as in variola.

It is, nevertheless, sometimes very difficult to distinguish between the two, particularly when the eruption in varioloid is confluent.

Smallpox is, as we have observed, accompanied by a rash, which may simulate a scarlatiniform eruption; the same happens in certain rare cases of diphtheria.

As a general rule, the eruption in scarlatina is found on the neck, in the armpits, the groins, in points where the skin is very delicate. The redness is diffused, and more marked or scarlet in certain points, contrasting with the color of the skin on neighboring parts, all being covered with sudamina.

The fever lasts eight or ten days, and when it falls, retrocedes gradually.

In all cases convalescence is very long and dangerous, because the least imprudence may become the starting point of complications of exceeding gravity.

About the twelfth day albumen is found in the urine, and if the child take cold a very grave attack of angina or fatal nephritis may supervene.

It must not be thought, because fever is no longer present and desquamation is taking place, that the malady is at end. The greatest care must be taken of the child, in order to prevent his taking cold; the room he is in should not be freely ventilated for a month; his skin is excessively sensitive, and a fetid atmosphere is better than a free supply of air, which, though pure, is cold. We should remember that, in ninety cases out of a hundred, just such imprudence has been the means of leading the little patient to the tomb.

In conclusion, after an attack of measles, the little patient should remain at least a month confined to the house; a period of two months is not too long after scarlatina and smallpox.

THE PRACTICE OF MEDICINE AMONG THE INDIANS.

BY H. M. M'CLENACHAN, M.D.,
Of Washington, D. C.

It shall be my aim to describe as clearly as possible the practice of medicine among the Indians, including in that term medicine, surgery and obstetrics. The writer has had the privilege of observing the customs of two tribes, to wit, Gros Ventres and Assinniboins. From information received from persons conversant with the customs of other tribes, I am satisfied the practices are essentially the same among all tribes not having been influenced by civilized ways.

In this article I shall confine my remarks to the practice of medicine proper, reserving the subjects of obstetrics and surgery for future numbers.

To know why the Indian believes in his mode of treatment (for he undoubtedly does), it will first be necessary to ascertain his views as to the cause and nature of disease.

He does not consider himself as in any way responsible for bringing on a spell of sickness. He may expose himself to inclement weather and contract a severe cold; but the two do not stand in the relation of cause and effect.

He knows certain diseases are contagious; but

he does not think the disease *per se* is catching, but that the person taking it is under some peculiar spell.

In a general way he does not consider that habits of life, changes of weather, or hereditary influences bear any relation to disease, but that it is governed by some higher power and entirely beyond the influence of man, so far as preventing it is concerned; but that an enemy can, by making bad medicine, cause it to produce sickness. All the manifestations of disease are, therefore, due to evil spirits.

They have no distinct idea of what they mean by the term, some giving to the spirits the form of animals or insects; others, again, consider them an imponderable entity. Whatever may be the peculiar form of the evil spirit imagined by the individual, all believe this much to be a fact, namely, that it takes possession of the body, causing sickness and death. It is a matter of observation among them, that there are many forms of disease, as whooping cough, measles, diarrhœa, etc., but they do not look upon the different forms as distinct types of disease due to specific causes, but simply believe the spirit to be inhabiting different parts of the body.

The spirit is omnipotent, therefore can produce convulsions in one and diarrhœa in another. It will thus be seen that they give no consideration to rational causes but assign everything to a higher power. I have asked them why it is that the spirit will select one instead of another, when the natural conditions were the same.

In case a child is sick, the father believes he has in some way offended the spirit, and it punishes him through his child, he being too strong for it. Again they say an enemy can influence the spirit. This is called making bad medicine. I have known of several cases where a man, having several wives, is taken sick, and where some one of the wives gets the blame for making bad medicine.

It is not necessary to multiply examples, for they would only prove what has already been asserted, that disease is caused by spirits. They give no distinct meaning to the term spirits. It is to them an all-powerful, always present *something*, capable of anything an imagination uncontrolled by reason can conceive of.

It will readily be imagined that the treatment will be essentially the same in all forms of disease. Such is the fact. Disease is an evil spirit, and the object in all cases is to drive it out of the body. Still they do employ other modes of treatment, but simply to relieve some local symptom and not to counteract the disease per se.

The treatment of the sick, except in cases of midwifery, is relegated to the "Medicine Man." He is a power among the Indians. They do not adopt the profession (if the term may be employed) from choice, but from a belief that they are called by some higher power. This call is not understood in the sense in which we employ it, but the person is supposed by them to have been instrumental in saving a life, and is thenceforward a Medicine Man. What medicines are used are collected and prepared by the Medicine Man, and their names and mode of preparation are profound secrets. The medicines they use are roots indigenous to the locality in which they reside.

The medicine man does not follow his calling from humanitarian motives, or for the love of science, but, like many in the civilized world, he believes the laborer is worthy of his hire. He has no stipulated fees, but takes all that he can get. His fees consist of horses, robes, wearing apparel, etc. He will take the last horse a man has. In justice to him, we must say, the Indians, as a people, exhibit the most remarkable disregard for property.

The treatment may conveniently be divided into two sections; the treatment of the disease, or, as they understand it, the spirit—and by treatment they mean the removal of the spirit; and second, the relief of symptoms.

To accomplish the first object, the medicine man decks himself in the most hideous costume. We will describe the average costume, premising with the remark that the dress varies with the number of articles procurable, the more the better. The face is painted, usually red, with yellow trimmings about the eyes and mouth. The hair, always worn long, has a tuft of feathers braided in on the crown, and to braids of hair hanging about the shoulders are attached horsehair, snake-rattles, shells, etc.; over all is dusted red and yellow paint. The ears are pierced by numerous rings, and suspended from them hang shells, reaching to the shoulders. About the neck are strings of bright-colored beads with birds' claws, pebbles, buffalo teeth, etc.

The wearing apparel consists of a shirt, made of muslin or raw-hide, leggings, breech-clout, moccasins, and over all a blanket or buffalo robe. The shirt is daubed with paint, with some hideous image on the breast. The leggins are made to fit closely, but with a wide strip along the outside, to which is attached beads, bones, etc. The blanket, or robe, in either case gaily adorned, is loosely thrown over the shoulders. Thus equipped, he is ready to go forth and terror-

ize the spirits. The patient is stripped and the performance commences. The medicine man goes through a series of gyrations and contortions, touching the patient with his hands, blowing upon the body, chewing roots and expectorating them over the body. The whole performance is involved in an air of mystery. Then comes the drumming, singing and dancing. For this there are two assistants, who beat the drums. The drums are simply hoops, about twelve inches in diameter, covered with rawhide, and having loose pieces of metal attached, to add variety to the sounds. The medicine man has a rattle, made of a bladder to which is attached a handle, and filled with pebbles. They gather around the victim, drum, rattle and sing, and keep up a constant to and fro motion of the body. The singing is easier imagined than described. If there is any music in it, I have never been able to detect it. I think the length of time occupied in these performances depends more upon the power of endurance of the actors than upon the condition of the patient. The number of repetitions varies with the condition of the patient and the ability to pay. The larger the fee the greater the influence the medicine man has over his patient. The Indian Doctor, in case the patient gets no better, protects his reputation very nicely, in that respect having the advantage over his white friend of the same profession. In some cases, it may be, the fee was not large enough. Again, some enemy has made bad medicine to counteract all his efforts. As a last resort, he may admit that he was not strong enough to scare the spirit.

Before leaving this subject, it may be of interest to some to learn of some of the tricks of the trade, for be it known the red man is not above deception.

He will console the patient by informing him that he hears the spirit, and that it has ceased its evil doings, and will soon depart. Or he may affect to see it in the air. No one is able to disprove the assertion.

Another very effective deception is to—as seen by those present—chew a bit of charred wood, and then place his mouth to the patient's body, and pretend to draw out the defunct spirit, and before the sick one's eyes to expectorate the blackened saliva.

We now come to the treatment of symptoms. They have learned, by observation, that it is necessary that the skin, bowels and kidneys should perform their several duties. Hence, when there is any derangement of these organs, they endeavor to correct it. As to the function of the skin, perspiration, they do induce that most effectually. Among all their practices, I know of none exhibiting so much ingenuity as the sweat-house. It is about eight feet in diameter, four feet high, and in shape like an inverted caldron. First they dig a hole in the ground, about one foot deep and eighteen inches in diameter. This is to be in the centre. Then around this, in the form of a circle is placed willow sticks, firmly planted in the ground and about two feet apart. They are about eight feet high, and all bent converging to a point in the centre, about four feet from the ground, and all securely fastened by willow twigs. Over this framework is placed blankets, several thicknesses being used, an opening being left for a door, which is closed during the sweating process. While this is being built, a fire has been kindled near by, and in it has been placed several small pieces of stone, to be heated. The persons who are to occupy the house, for several take a sweat at the same time, now divest themselves of all clothing, enter and seat themselves, tailor fashion, around the centre. A pipe filled with tobacco and lighted is then given them. An assistant now removes the heated stones with two sticks, and places them in the hole in the centre of the house, hands to those inside a bucket of water, and closely closes the door. The water is poured over the stones, when a volume of steam and heated vapor arises, filling the apartment. The bathers then smoke, and sing, and sweat, and sweat, and sing, and smoke. They remain inside about fifteen minutes when they are bathed in a profuse perspiration.

If it be not freezing weather, the bathers go from the bath to the river and plunge in, for I should have mentioned that the sweat-house is built near a stream of water. Strange as it may seem, I have not seen any immediate serious effects from such a sudden change, forcing, as it must, a large amount of blood from the surface to the internal organs.

It is the custom of many to take frequent baths, not for the relief of any malady, but on general principles. During the winter season these sweat-houses are erected inside buildings; then, of course, the cold plunge is dispensed with.

For producing catharsis certain roots are used, but I have not been able to learn the names of any of these roots. As they are always given in the form of a decoction, I am inclined to ascribe more virtue to the menstruum than the drug. The object is also sometimes accomplished by a process of kneading, which excites the peristaltic movement of the bowels. I have heard of the syringe being used (one made from pithy

wood) but among the Indians I have observed I have never seen it used.

In case of suppression of urine, the Medicine Man would first drum and sing, then resort to the following:—

Heat small pieces of stone, wrap them in flannel and place them under the patient's back. In case of failure, then the steam-bath would be resorted to. Here, it may be observed, the treatment is not so wide of the mark.

The Indians have great faith in emesis. I do not know why it is they should resort to this in some cases and not in others. As a rule, this procedure is confined to children. It is accomplished by the use of decoctions. The theory of the treatment is that if the spirit has made any bad medicine in the stomach, it can be gotten rid of.

The Indian has no faith in a medicine the effect of which he cannot see. The Medicine Man never gives any drug to be taken at regular intervals.

Such is a brief outline of the Indian's conception of the cause and treatment of disease.

In our next we will take up the subject of surgery.

DIPSOMANIA.

BY M. J. HALLORAN, M.D.,
Of Worcester, Mass.

Bruhl-Cramer, a German physician, practicing at Moscow described under the designation *Trunksucht*, an affection sometimes observed in habitual drunkards, where the appetite for liquor becomes so urgent that nothing will allay it. At present, under the designation dipsomania is understood a form of mental disease, having as prominent symptom a morbid craving for drink, utterly beyond the power of the patient to control.

As Esquirol has pointed out, the patient may be noted for sobriety, even for his disgust for alcoholic stimulants, but at the moment of the access no respect for himself, for his relations or his position in society will prevent him from drinking. Often there are intervals of perfect sobriety. Esquirol records the case of a merchant who became dipsomaniac every winter; during the continuance of the attack nothing was spared, and he reduced himself almost to beggary, but once the attack was finished, he returned again to business, and made good his losses. In the great proportion of cases these sober intervals become shorter, and sometimes the mad passion for drink seems to continue without lucid interval. (Fletcher—*Brit. Med. Jour.*, 1864.)

There is an acute form of dipsomania observed in persons predisposed to mental derangement on the occurrence of any great moral commotion, at the time of the change of life and during the puerperal state in women, or during the prodromal period of general paralysis or insanity in men.

In persons predisposed hereditarily to mental trouble, small quantities of alcohol soon induces a condition of veritable dipsomania; but it will generally be found that there exists in such individuals other evidence of a morbid mental condition, tendency to suicide, pyromania, etc.

"There is something wanting;" they all belong to the great class of degenerated beings (êtres degenerèes) on which Morel has so well written; they constitute the various classes of monomaniacs, a consideration which has led Skae to class dipsomania as one of the forms of moral insanity.

He remarks (Edinburgh *Med. Journal*, 1858, p. 772): "This craving for stimulants is only one of the symptoms of moral perversion which characterize the disease;" and again, "Of the other symptoms of moral perversion, the most common is the habit of lying; and accompanying this disregard for the truth, there are often other indications of moral perversion in the insane drunkard; such are extreme licentiousness, or a propensity to theft, or a delight in fomenting quarrels and creating mischief by leading other parties into trouble."

But there are other clinical facts which have not attracted the attention they merit.

I laid before M. Magnan, of the St. Anne Asylum at Paris, the objections made by Bucknill to clinical observations of dipsomania in general and in particular to the one M. Magnan had, quoting from the elder Trélat, reproduced in his work on Alcoholism. It was the case of a lady whose mother and uncle had been subject to attacks of dipsomania. She led herself a very exemplary life, but from time to time entered on wild periods of drunkenness, during which friends, honor and family were forgotten. During these attacks she introduced all manner of nauseous substances into the liquor, in order to induce disgust of it, but without success. Dr. Bucknill contends that there is nothing to prove that she was not a common drunkard, given to periodical sprees, and rather takes to task M. Trélat for giving credence to her assertions of attempting to render the liquor nauseating.

M. Magnan replied to this objection: "The patient, previous to an attack of dipsomania, is just like the ordinary insane patient, distressed,

plunged into profound melancholy, a prey to groundless fears." As M. Trélat observes (*de la Folie lucide*, p. 151): "Drunkards drink when they find a favorable occasion; in dipsomania the patient drinks only at the moment of the access."

Some men attend well to business during the day, but drink heavily at night; others drink on public occasions, or when driving a bargain; they drink, as M. Trélat says, when a favorable occasion offers.

How different the dipsomaniac: he may have every day liquor under his hands with no desire for it; at the moment of the access he will have recourse to every subterfuge to obtain liquor, and if deprived of it will swallow anything in the guise of a stimulant.

A young lady patient of Dr. Skae's drank creasote and vinegar, and even took tobacco, when deprived of everything else. And, unfortunately, such patients become dangerous while under the influence of liquor; a patient of Gall's became an incendiary only at such moments.

In the great majority of cases morbid hereditary antecedents exist; in thirty-two out of sixty-eight cases, according to Skae; such was also the case in several among the patients we observed at the St. Anne Asylum. We have found also that the patient was generally subject to other morbid impulses; one patient made three determined attempts at suicide; another was arrested twice in succession for petty thefts in public, giving more or less plausible reasons therefor.

These patients generally drink alone; they are often intensely ashamed of the vice; one patient used to immediately quit any house where she was discovered, leaving her furniture behind, and never returning to claim it.

The reasons given by these patients for their actions seem plausible, and they will make the most solemn promises of reform, which are invariably broken.

We consider, then, with Dr. Skae, that dipsomania is one form of moral insanity, but that it is of difficult diagnosis; it has been too much the habit of late years to style inveterate drunkards "dipsomaniacs." Careful investigation should be instituted as to whether there exists any hereditary morbid tendency, or whether the ordinary actions of the patient give any indication of mental derangement.

As Morel remarks (*Etudes Cliniques*, p. 333), "In such patients we recognize an unhappy organization tainted with morbid hereditary tendency, and destined to finish miserably in general paralysis or dementia."

ICTERUS NEONATORUM AND ITS RELATIONS WITH UMBILICAL HEMORRHAGE.

A Paper read before the Atlantic County Medical Society, Atlantic City, N. J., February, 7th, 1881,

BY BOARDMAN REED, M.D.,

Of Atlantic City, N. J.

One of the most serious accidents that can befall an infant within the first week or two of its life is spontaneous hemorrhage from the umbilicus. This is fortunately a very rare mishap. Among 2000 births at the Emigrant's Refuge, Ward's Island, only two cases of this affection occurred. There was only one case, it is said, in upwards of 9000 children cared for during two years at the Foundling Hospital, Paris. Two old and eminent practitioners in this country, one of whom assisted at 3000 and the other at 4000 births, report having seen only a single case each of this form of hemorrhage. It is stated that in the Dublin Lying-In Hospital not even one case occurred during twelve years, among 6654 births. All the records to which I have had access show the great infrequency of this affection. It has happened to me, however, to have two well-marked cases of it within the last three years. In both of these the hemorrhage was persistent for several days, and was complicated by jaundice; and in both it was fully controlled, though in one of them the child died some ten days later.

These cases I shall proceed to report somewhat fully, on account of the rarity and serious nature of the disease, and in the hope that other members of the Society may, from their own experience, be able to throw additional light upon the subject.

Case 1.—November 16th, 1878, a male child, born at full term, well-formed and in good flesh, weighing about eight pounds. The mother seemed to be in fairly good health, though coming of a family having a strumous tendency. There were no indications of syphilis in either parent, or in the appearance of the child. The cord dropped on the sixth day and the base apparently healed as usual. About the tenth day jaundice set in and became marked, but yielded gradually to minute doses of blue pill. On December 5th, when the child was nineteen days old, I was called in to prescribe for an oozing of blood which had then been progressing a day or two. The jaundice was now disappearing. A little blood came from the reopened surface of

the umbilicus, enough to stain the compresses as often as placed in position. Some simple astringent application was made, and this proving ineffectual, benzoated oxide of zinc ointment was ordered. This stopped the bl eding and healed the open surface within a few days. The child was nursed by the mother, and is still living, being one of the most robust looking children in the place.

Case 2.—This occurred nearly a year later, and was in several respects highly interesting. The mother had been afflicted for a year or more with anæmia, palpitation of the heart and other symptoms of deranged nutrition, and a few months subsequent to the birth a vaginal examination revealed marked cervical endometritis, with some areolar hyperplasia.

The father had long suffered from impaired health, having dyspepsia, periodical sick headaches, and considerable nervous exhaustion.

During this pregnancy the mother had nausea almost constantly, which became aggravated in the later months, so that vomiting was frequent, and very little food could be retained. Finally the vomiting became almost incessant. No remedy afforded even temporary relief, except hypodermics of morphia, which checked it usually for a period of eight to twelve hours.

I had ordered rectal alimentation to be resorted to, and was on the point of cauterizing the *os uteri*, as the only alternative to the induction of premature labor, when nature interposed, and a female child was delivered a month before the time expected. Judging from the appearance of the child, however, the birth must have taken place within a week or two of the expiration of the full term.

A week previous to the birth hemorrhage began from the uterus, though the *os uteri* was not then dilated. This was temporarily suppressed by the usual measures, but recurred at intervals until the child was born, Sept. 5th, 1879. It was alive and appeared in fair condition, weighing about six pounds.

The mother had no milk, or next to none, and all measures failed to increase the secretion; so that artificial food had to be depended upon. This was, of course, a particularly unfavorable circumstance, considering the inherited tendencies of the child.

The cord was secured with a double ligature, and all went well until early on the morning of Sept. 8th, the fourth day, when the compress over the umbilicus was discovered to be saturated with blood. The nurse finding the ligature secure, attempted to stop the bleeding by applying cobwebs. This failed entirely. Upon being called I found blood issuing slowly, but continually, from the sides of the softening cord, in various places. I immediately applied a new ligature, within an inch of the navel, but this was of no avail, the blood continuing to ooze from all parts of the base above it. I now applied a styptic, composed of Castile soap, chlorate of potash and alcohol, and made firm compression. The bleeding was only temporarily checked.

I proposed resorting next to Monsell's salt, and should that have failed, to ligation of the umbilicus *en masse;* but being called out of town, I left the case with Dr. Wm. H. Bennett, who, after trying in vain several styptics, inserted harelip pins through the tissues beneath the umbilicus and ligated the mass.

Upon returning next day I found the hemorrhage greatly diminished, and after some further tightening of the ligatures by Dr. Bennett and myself, and the administration of ergot with tincture of the chloride of iron, in suitable doses, it still further lessened and finally ceased altogether.

It should have been mentioned that before the hemorrhage was controlled spots of purpura appeared upon the forehead and other parts of the child.

Jaundice was not noticed at the time the hemorrhage began, but was developed a few days subsequently, to a marked degree, while in *Case* 1 it preceded the bleeding by some days.

On September 15th the pins were removed, and by the 18th the umbilicus had healed completely.

Shortly after the pins were removed, Dr. Bennett, who had been seeing her with me, returned to Philadelphia. When the life of the child was so seriously threatened, a young mother stopping in the neighborhood, who had a full breast of milk, came in and nursed it several times a day. This no doubt contributed largely to the success of our measures for stopping the hemorrhage, since, when this lady left the place and the child was put again on cow's milk, diarrhœa set in and the jaundice became more marked. The bowels were checked by the aid of mild astringents and a change to condensed milk, but the child continued to fail steadily, became very weak, vomited frequently, and died September 21st, with symptoms of general adynamia.

I can learn of only one other case of spontaneous hemorrhage from the cord as having happened in Atlantic City. This occurred three or four years ago, in the practice of a homœopathist here. The bleeding, as I am informed, set in

suddenly, on the tenth day, after the cord had separated normally, and proved uncontrollable. To supplement the efforts of the attending physician the assistance of a resident surgeon was invoked, but neither the infinitesimal doses of homœopathy nor the most potent styptics applied by a skillful hand were of any avail, and the little one soon succumbed. This case presented no jaundice.

There have been previously reported, so far as I am able to ascertain, only one hundred and ninety-six cases of spontaneous umbilical hemorrhage. Jaundice was observed in seventy of these, purpura in seventeen, and ecchymosis in five. The three additional cases I here report bring up the total number to one hundred and ninety-nine, in ninety-four, or nearly one half, of which there was some manifest outward indication of vitiated blood.

Counting my second case among the fatal ones (though death did not result until some ten days after the hemorrhage was controlled), the total number of deaths in the one hundred and ninety-nine cases was one hundred and sixty-five, or about eighty-three per cent.

Dr. Wm. B. Atkinson, in his little work entitled "Hints in the Obstetric Procedure," published in 1879, presents a brief but comprehensive account of umbilical hemorrhage and the various forms of treatment best adapted to it. In all serious cases he advises the ligature *en masse*, with the local application of styptics afterward, in addition. The method of performing this simple operation is to transfix the integument merely by passing harelip pins through under the base of the umbilicus, at right angles to each other. Then several figure of-eight turns are made with a waxed ligature around the pins or entirely underneath them, thus ligating the entire mass very effectually.

In a small proportion of cases, even when there is present what is called a hemorrhagic tendency, this may succeed, but more often the bleeding, even if checked in this one place, breaks out in another, perhaps in some of the viscera, and death then invariably results.

One of the most interesting features of this rare affection is its frequent association with jaundice. Dr. Charles West, in his classic work, refers to this connection, though having never observed it himself. Speaking of "Icterus Neonatorum," he says:* "One remarkable phenomena attending these cases is the tendency to hemorrhage by which they are characterized; this hemorrhage taking place, for the most part, from the umbilicus, either before or soon after the separation of the funis. * * * It is unusual for the infant to survive its birth longer than a fortnight."

Ellis, in his "Diseases of Children," speaks of jaundice as "not an uncommon prodroma" of hemorrhage from the cord.

There have been various theories to account for the frequent association of these two conditions, none of them wholly satisfactory. It is evident enough that in the grave cases of bleeding there is a hemorrhagic diathesis, as all the authors take pains to state; but this really explains nothing. There is evidently some impairment of the blood, which becomes abnormally fluid, and it is probable that various causes are capable of producing such a dyscrasia in young infants. Inherited tendency must be a possible predisposing cause, since instances are on record of three children in one family dying from the form of hemorrhage now under discussion. Possibly also obstruction of the bile ducts or a deficient secretion of bile, at an age when the weight of the liver bears twice as great a ratio to the weight of the entire body as in adult years, and when, presumably, that organ performs functions of relatively greater importance than at a later period, may vitiate the blood sufficiently to affect its coagulability.

Comparatively recent investigations—notably those of Austin Flint, Jr.—have shown that the liver performs an important excretory function in separating from the blood the substance known as cholesterine. This, unlike most of the other constituents of the bile, is now believed to be purely excrementitious, being analogous to the urea excreted by the kidneys. Just as the retention and accumulation of urea in the system produce the condition called uræmia, the like accumulation of cholesterine, through failure of the liver to excrete it, produces a group of toxic symptoms, to which the name cholesteræmia has been given. This is a true blood poisoning, and when it is produced artificially, as it was by Koloman Müller, in 1873, in five experiments on animals, there is set up a complete representation of the phenomena of grave jaundice. Furthermore, in numerous cases of jaundice occurring in the course of cirrhosis or other fatal forms of disease, an excess of cholesterine has been found in the blood by Dr. Flint, while similar experiments made upon the blood of persons affected with simple jaundice due to duodenitis, revealed no such excess of that substance. Yet the latter cases usually presented the same decoloration of the fæces, and even more marked pigmentation

* First edition, Phila., 1850, p. 354.

of the skin and various secretions than in the fatal forms. This would seem to prove that, not the pigment, but some other ingredient of the bile must be the real toxic element in jaundice.

There are not at present sufficient data—at least not in my possession—to warrant the inference that the particular form of blood poisoning due to the accumulation of cholesterine in the system in consequence of a suppression or perversion of the functions of the liver, is that which in new born infants causes a hemorrhagic tendency; but this is not impossible, since in the graver forms of jaundice, at all ages, the immediate cause of death is frequently hemorrhage, and in those affections a notable excess of cholesterine has been shown to be present.

Yet in all these cases the jaundice, as well as the excess of cholesterine may be only an effect, not the cause, of blood poisoning, some derangement of nutrition being the first link in the chain. There are malignant forms of jaundice, which are generally held to result from blood poisoning, such as those occurring in pyæmia, and from snake poisons, over-doses of phosphorus, etc. Even in these cases, however, it is probable that the toxic matter, in whatever way it enters the system, first produces some disturbance in the functions of the liver before the symptoms of jaundice result. It is by no means certain that the pathology and etiology of jaundice have been yet fully and correctly wrought out.

Virchow, has lately advanced the view that jaundice resulting from poisoning by phosphorus is really due to obstruction, being caused by catarrh of the duodenum and the partial closure of the orifice of the ductus choledochus. Other German observers now object to the division of icterus into two classes, *hepatogenous* and *hæmatogenous*—that is, cases referable to the liver and those referable to the blood—maintaining that all cases may arise from either faulty action of the liver, or from obstruction of its ducts. When the liver, after death, is found anatomically intact, they hold that there may have been spasmodic closure of the bile ducts, or a lowering of the blood-pressure in the hepatic capillaries, causing a decrease, or even suppression, of the biliary secretion. To this latter cause they attribute the jaundice of starved animals, and that which follows a free discharge of bile through a fistulous opening. They suppose that icterus neonatorum may be due to lowered blood pressure in the liver, resulting from the closure of the umbilical vein, which during fœtal life emptied the main bulk of the oxygenated blood directly into that organ. This hypothesis obviously might account for the transient attacks of jaundice, so often seen in the new-born, which are not connected with hemorrhage or any blood dyscrasia. Just as obviously it would not account for the graver cases which usually terminate fatally, unless it be supposed that there is some serious obstacle to the establishment of the circulation in the new channels at the time of birth. Even this hypothesis would utterly fail to account for cases which do not develop until the tenth day, or later.

Considering all the facts, we are driven to the conclusion that there may be various causes of icterus neonatorum, as of jaundice in the adult, and that when it is associated with hemorrhage there must be some impairment of the crasis of the blood. What it is that poisons the blood has not been conclusively established, but probably it is the accumulation in it of excrementitious matters, which are normally separated by the liver and discharged through the intestinal canal.
